1.1 Introduction

1.2 What is this thesis about

This thesis is about Fanos with torus actions.

PRELIMINARY DEF (see main def)

The basic aim is the classification of such Fanos in specific cases. This is an absolutely hopeless task. Nevertheless, it divides naturally into finite subtasks as follows.

1.2.1 Log del Pezzo surfaces of complexity 1

The (Gorenstein) index is .. (see Def ??). For any given picard rank $\rho \in \mathbb{N}$ and index $i \in \mathbb{N}$, the set of deformation families of log del Pezzo surfaces X with $\rho_X = \rho$ and $i_X = i$ is finite . In this thesis, we present an algorithm that, for given ρ and i , lists certain types of degenerate fibre in each such family, thereby providing a classification of all families.

It is worth noting that the number of families increases enormously as picard rank and index increase. For example, only in the toric case, the start of the classiciation is

TABLEOFINCREASINGNUMBERSFROMGRDB

We consider them from three different and related points of view.

In particular, we classify log del Pezzo surfaces that admit a \mathbb{C}^\times action. In this thesis we give an algorithm to classify log del Pezzo surfaces that admit a \mathbb{C}^\times action and which have only log terminal singularities.

A variety X of dimension n equipped with an action of a torus of dimension $n - k$ is referred to as a variety of complexity k ; see Definition ?? for the precise definition. To illustrate the notion, note first that a toric variety X has an action of its n -dimensional ‘big torus’ $T \subset X$, and equipped with this action X is a variety of

complexity 0. One could also give consider X equipped with the natural action of a k -dimensional subtorus $T' \subset T$, and then X is a variety of complexity k . (See §??.)

However, there are many varieties of complexity $k < n$ whose torus action does not extend to a toric variety. In fact, there is a nice combinatorial way of determining whether or not such an action can be extended to a higher-dimensional torus. This is one of the main themes of this thesis: we study and classify surfaces of complexity 1 that are not toric.

In this way, complexity provides a way of grading the difficulty of a classification problem. Significant progress has been made on this problem before: Süß ? classifies log del Pezzo surfaces admitting a \mathbb{C}^\times action which have picard rank one and Gorenstein index less than 3. Huggenberger ? classifies log del Pezzo surfaces of complexity 1 that have index 1 and arbitrary picard rank. Ilten, Mishna and Trainor ? recover the same classification and extend it into higher dimension. The methods and language used are broadly the same (though, in the language of toric geometry, it varies whether papers work in the lattice N or its dual lattice M), though Huggenberger exploits Hausen’s anticanonical complex technology to describe the Cox ring in detail.

We extend these existing results by presenting an algorithm that classifies log del Pezzo surfaces of complexity 1 with given picard rank and index. The algorithm works and terminates *for any* picard rank and index, though since the index is an unbounded invariant, there is no hope of a closed-form classification of all such del Pezzo surfaces. In Section ??, we show the previous fits into our results and algorithm.

===

1.2.2 Bounded singularity content of log del Pezzo surfaces

Another feature of log del Pezzo surfaces is the type of singularities that they have. It follows from the definition (Def ??) that the singularities are all finite quotient singularities, but this itself is an infinite set.

The *discrepancies* associated to a singularity (see Def ??) form a measure of its complexity expressed as a collection of rational numbers, one for each curve in a resolution. When these numbers are small, the singularity may be regarded as ‘more complicated’. However, in exactly this case, the surfaces can be explicitly classified: informally, the basic reason is that it is hard to impose many of these singularities onto a single surface.

These conditions naturally arise as soon as you start to consider singularities in families. The first place this was considered was in ? where they considered the case of $\frac{1}{p}(1, 1)$ singularities, where $p \geq 5$. We extend this by

Theorem 1.2.1 (= Theorem ??). *Let X be a surface with singularities of only small discrepancy then X has at most one singularity except for one sporadic family. All for these log del Pezzo surfaces admit a toric degeneration.*

This reproves the results of ? and proves bounds on the singularities established in ? case where the log del Pezzo surface admits a toric degeneration.

We also consider how the cascade of these surfaces behaves. This notion was introduced in ? and is essentially asking for the birational relations between the surfaces. We prove that once our singularity is sufficiently complicated then you get the foll-

lowing series of birational relations

$$\begin{array}{c}
X_1^0 \xleftarrow{\phi_1^1} X_1^1 \xleftarrow{\phi_1^2} \dots \xleftarrow{\phi_1^{a_1-2}} X_1^{a_1-1} \\
\qquad \qquad \qquad \swarrow \phi_1^{a_1-1} \\
X_2^0 \xleftarrow{\phi_2^1} X_2^1 \xleftarrow{\phi_2^2} \dots \xleftarrow{\phi_2^{a_2-1}} X_2^{a_2-1} \xleftarrow{\phi_2^{a_2}} X_1 \xleftarrow{\Phi_1} X_2 \xleftarrow{\Phi_2} X_3 \\
\qquad \qquad \qquad \searrow \phi_3^{a_3-1} \\
X_3^0 \xleftarrow{\phi_3^1} X_3^1 \xleftarrow{\phi_3^2} \dots \xleftarrow{\phi_3^{a_3-2}} X_3^{a_3-1}
\end{array}$$

1.2.3 Smoothings of log extemal extractions

To fit with the ongoing interest in toric degenerations, we study the case of a log terminal cyclic extractions from a given singularity. These are maps $f: Y \rightarrow X$ with relative Picard rank one, such that both X and Y only have cyclic quotient singularities along with other technical conditions. We prove the following:

Theorem 1.2.2. *Let $f: Y \rightarrow X$ be a cyclic extraction in dimension two then both Y admits a toric degeneration which Y_Σ which extends map f to $f_\Sigma: Y_\Sigma \rightarrow X$*

We then characterise these possible toric degenerations, and extend this in part to higher dimension. We also provide several examples of how this can be applied to the global case. In addition in dimension greater than or equal to three we discuss how this gives explicit equations for every single possible deformation of the toric variety. In addition we show how this relates with notion of focus-focus singularities and the SYZ fibration in dimension 2.

Chapter 2

Technical details

Nothing in this chapter is original work, and references are provided. Throughout this thesis we work only over the field \mathbb{C} .

1.1 Toric Geometry

We use the traditional language set up in ?. In particular we use the fact that a normal toric variety X of dimension n can be associated with a (non unique) fan $\Sigma \subset N \cong \mathbb{Z}^n$. We consider the dual lattice to N , denoted M . Any $m \in M$ corresponds to a character of the torus which in turn corresponds to a monomial function in the function field of X . We denote the 1-skeleton of one dimension cones in Σ by Σ^1 . We also use this to refer to the set of primitive vectors generating those rays; this is a small abuse of notation that is always clear in context. We say a fan is complete if every lattice point $u \in N$ lies inside some cone $\sigma \subset \Sigma$. The associated variety to a complete fan is complete.

1.1.1 Cox rings

Given a toric variety X , we wish to construct it as a GIT quotient. We follow the construction of ?. Given a complete fan Σ with $\Sigma^1 = \{v_1, \dots, v_m\}$, we consider the toric variety given by a fan $\bar{\Sigma} \subset \mathbb{Z}^m$, with $\bar{\Sigma}^1 = \{e_i\}$, where e_i are the standard basis vectors. A set $\{e_i\}_{i \in S}$ spans a cone in $\bar{\Sigma}$ if and only if the set $\{v_i\}_{i \in S}$ spans a cone of Σ . The variety Y associated to $\bar{\Sigma}$ is a subset of K^m . By construction we have a well defined map of fans $\phi: \bar{\Sigma} \rightarrow \Sigma$ corresponding to a linear projection. This induces a map $\tilde{\phi}: Y \rightarrow X$ which can be seen as a GIT quotient with weights corresponding to the linear dependencies of Σ^1 , and a finite group corresponding to the index of the sublattice of N generated by Σ^1 .

1.1.2 Cyclic quotient singularities and singularity content

We also make frequent use of the following concepts introduced in ? and ?. Suppose given a cyclic quotient singularity $S = \frac{1}{r}(a, b)$ in two dimensions. Here S is the quotient of \mathbb{C}^2 by the group $G \cong \frac{\mathbb{Z}}{r\mathbb{Z}}$, with action defined by the matrix

$$\begin{pmatrix} \zeta^a & 0 \\ 0 & \zeta^b \end{pmatrix}$$

where $\zeta = e^{\frac{2\pi i}{r}}$. Without loss of generality a and b are coprime to r . This in turn implies that, by change of basis, we can write S as $\frac{1}{r}(1, u)$. The minimal resolution of this singularity is a chain of curves C_1, \dots, C_n with self intersections equal to $[a_1, \dots, a_n]$, where these values a_i are equal to the coefficients of the Hirzebruch Jung continued fraction of $\frac{r}{u}$, as laid out in ?.

We are mainly interested in studying the restricted class of deformations known as \mathbb{Q} -Gorenstein as given in ?.

Definition 1.1.1.

Singularity content is a concept introduced in ?? as a \mathbb{Q} -Gorenstein deformation

invariant of a surface. Given a surface singularity S we define the index one cover S_1 to be the quotient of \mathbb{C}^2 by the subgroup $H = G \cap SL_2(\mathbb{Z})$. This gives $\mathbb{C}^2 \rightarrow S_1 \rightarrow S$ where S_1 has a singularity of type A_n , and this has equation $xy = z^{n+1}$. The group G/H acts on S_1 with quotient S . That is, this group acts on $xy = z^{n+1}$ with some weight k ; this means $G/H \cong \frac{\mathbb{Z}}{n\mathbb{Z}}$ acts naturally by some weights on the x, y, z and the equation has weight k . This gives us the \mathbb{Q} -Gorenstein deformations of S are the quotients of the equivariant deformations $xy = \sum a_i z^{k+i\frac{r}{n}}$. This is smooth if and only if $k = 0$. On the other hand if $k \neq 0$ the deformation has a residual singularity $\frac{1}{r}(a', b')$. We call the pair $(n, \frac{1}{r}(a', b'))$ the singularity content. If $n = 0$ we say the singularity is \mathbb{Q} -Gorenstein rigid. The value n can be seen to be equal to the topological Euler number of the \mathbb{Q} -Gorenstein smoothing with the singular point removed, although this is not used in this thesis.

Given a log del Pezzo surface X with only \mathbb{Q} -Gorenstein rigid singularities, we define the singularity content $(n, \{S_1, \dots, S_n\})$ where S_i are the singularities of X and n is once again the topological Euler number of $X^0 = X - \{\text{Singular locus of } X\}$. In ? we show how the value n fits into the language of affine manifolds.

1.2 Log del Pezzo background

1.2.1 Definitions

We here relate some basic definitions and facts about surfaces.

Given a normal surface singularity S and minimal resolution $\pi: \tilde{S} \rightarrow S$ then we have

$$K_{\tilde{S}} = \pi^*(K_S) + \sum a_i E_i$$

Definition 1.2.1. *Throughout this thesis a log del Pezzo surface is a normal complex projective surface with log terminal singularities and $-K_X$ ample.*

Where we say a singularity is

- terminal singularities if $a_i > 0$
- canonical singularities if $a_i \geq 0$
- log terminal singularities if $a_i \geq 0$
- log canonical singularities if $a_i \geq 1$

A surface singularity is log terminal if and only if it can be constructed as a quotient of \mathbb{C}^2 by a, not necessarily cyclic, group action ???. The classification of smooth log del Pezzo surfaces have been classified as the blowups of \mathbb{P}^2 at less than 9 general points.

Given an orbifold log del Pezzo surface we frequently use the invariants $-K_X^2$ and $h^0(-K_X)$. These can be via orbifold Riemann Roch as set out in ??. For a rough sketch of how we do these calculations, given a singular X , with minimal resolution Y . Then $-K_Y^2$ and $h^0(-K_Y)$. To account for these the contractions, there is a correction term which we calculate via toric geometry, in the case of case of $-K_X^2$ this corresponds to the area of lattice cones contained in N corresponding to the singularities and in the case of $h^0(-K_X)$ this corresponds to a count of lattice points in the dual of the cone inside the lattice M . These are invariant under \mathbb{Q} -Gorenstein deformation.

1.2.2 Hirzebruch Surfaces

We briefly state some basic results about Hirzebruch surfaces ??. A Hirzebruch surface is a rational scroll defined as the quotient of \mathbb{C}^4 by $(\mathbb{C}^*)^2$ with weights $(1, -1, 0, 0)$ and $(n, 0, 1, 1)$. Alternatively it is the minimal resolution of $\mathbb{P}(11n)$. From this we see that we have the picard group generated by B and F , where $B^2 = -n$ and F is a fiber of the map to \mathbb{P}^1 . From this it is straight forwards to see the possible smooth rational curves on a Hirzebruch surface, let $A = B + nF$ then every smooth reduced rational curve lies in one of the linear equivalence classes $|A|$, $|2A|$, $|A + F|$, $|A + 2F|$, $|B|$, $|F|$ and $|2F|$.

1.2.3 Basic Surfaces

We finish with a very brief overview of [1], [2] and [3] as some of the methods we employ are similar. Respectively these papers classify log del Pezzos with singularities with minimal resolution [3] in [1], [3, 2] and [3] in [2], and finally one singularity with resolution $[n]$ in [1]. The structure is similar, classify the possible surfaces X which admit no Mori contractions to another surface which could arise from these choices of singularities. These are called basic surfaces. Then study their blowups and their birational relations, often in the context of cascades as introduced by [1]. Via these explicit classifications they have been able to give explicit coordinate constructions and their toric degenerations (when they exist). In Chapter 2 we classify log del Pezzo surfaces with singularities of the form $[a_1, \dots, a_n]$ with both a_1 and a_n greater than two via similar although modified methods.

1.3 Gross Siebert

In this section we do not use or even refer to the full power of the Gross-Siebert program, we are mainly using results referencing how certain SYZ fibrations are constructed and how these give rise to toric degenerations. Our main reference throughout is [1], mainly chapters 1.4 and 1.5. We have made a variety of small changes to notation, namely our fans lie inside N instead of M to be consistent with the rest of the notation within the thesis and we do not consider fans on non compact affine manifolds.

We start with the definition of a tropical affine manifold

Definition 1.3.1 ([1] 1.22). *A tropical affine manifold is a real topological manifold (possibly with boundary) with an atlas of coordinate charts such that every transition function lies in $N_{\mathbb{R}} \rtimes GL(N)$.*

and then allow singularities on this tropical manifold is a manifold B and a codimension two or more locus Δ such that $B - \Delta$ is a tropical affine manifold.

We finish by extending the definition of a fan to lie on tropical affine manifolds with singularities. We a collection of cones Σ on a tropical affine manifold B is a fan, if it satisfies the usual condition of a fan in a lattice N and the condition that locally around every cone $\sigma \in \Sigma$ there is embedding of σ into a lattice. For the full technical definition see [1.26]. Now given a surface X such that the minimal resolution Y can be constructed from a toric variety Z_Σ by blowing up points on the boundary we show how this related to a fan on a tropical affine manifold. Denote by C_i a curve in the boundary of Z_Σ , and $\rho_i \in N$ the corresponding ray in Σ . If we blow up C_i k times then we introduce k singular points along the ray ρ_i each with monodromy $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ in a basis u_i, v_i with u_i being the primitive generator of ρ_i . This gives a fan Σ' on a singular integral tropical manifold, such that when we look at the self intersection of the divisors D_i corresponding to rays we have exactly the same values as on the boundary of Y .

We now sketch out the discrete Legendre transform, in [?] this is defined with respect to a polarisation. For the sake of brevity we ignore this technicality, however for a complete definition see [?] section 1.6 has a complete definition. We define the discrete Legendre transform of a fan Σ on a tropical affine manifold with singularities to be the integral tropical affine manifold with boundary such that the normal fan to each face is Σ . The classical example is the del Pezzo surface of five.

Chapter 2

Small Discrepancy

2.1 Context

The main result of this chapter is

Theorem 2.1.1. *Let X be a non-smooth log del Pezzo with only singularities of small discrepancy. Then*

1. *X has either one singularity or two singularities, and if there are two each of them are of type $\frac{1}{p}(1,1)$ for some, possibly different, p .*
2. *If X admits no floating -1 -curves then X admits a toric degeneration.*

This is a first draft, context will be inserted

2.2 Standard notions and notation for quotient singularities

2.3 Singularities with small discrepancy

Recall from Section 3.2 our standard notation for quotient singularities. We consider the germ S of a cyclic quotient singularity appearing at a point P on a projective surface X . The minimal resolution of X is denoted $f: Y \rightarrow X$. It contains a chain of exceptional (smooth, rational) curves C_1, \dots, C_n , entirely determined by S itself, which are ordered so that the only intersections between these curves are $C_i \cap C_{i+1}$ which is a single transverse intersection for each $i = 1, \dots, n-1$; in other words, C_1 and C_n are the two ‘ends’ of the chain. We also denote the discrepancies of each C_i (as curves in Y) by $d_i \in \mathbb{Q}$: thus

$$K_Y = f^*(K_X) + \sum_{i=1}^n d_i C_i.$$

We introduce a property of cyclic quotient singularities that is central to the rest of the chapter.

Definition 2.3.1. *Let S be a cyclic quotient singularity, and C_1, \dots, C_n the exceptional curves of the minimal resolution of S and d_1, \dots, d_n their discrepancies, as above. We say that S is a singularity with small discrepancy if $d_i \leq -\frac{1}{2}$ for all $i = 1, \dots, n$.*

To simplify our calculations we introduce to the notation $e_i = d_i + 1$.

Proposition 2.3.2. *In the notation above, a singularity S has small discrepancy if and only if $C_1^2 \neq -2$ and $C_n^2 \neq -2$ and $S \not\cong \frac{1}{3}(1, 1)$.*

Proof. We use the fact that the discrepancy is a strictly decreasing sequence then a strictly increasing sequence. So it suffices to show this for C_1 and C_n and then

apply this to show it for the intermediate values. We use the following formula for the discrepancy $e_i = \frac{e_{i-1} + e_{i+1}}{a_i}$. We note that if $a_1 \geq 4$, then as $e_0 = 1$ and $e_2 \leq 1$ we have $e_1 \leq \frac{2}{-4}$. This implies the inequality for small discrepancy. In the case where $a_1 = 3$ this results in the following, as $e_1 \geq e_2$ by substituting e_2 into $e_1 = \frac{1+e_2}{-3}$ we get $e_2 \leq \frac{1+e_2}{-3}$ rearranges to $2e_2 - 1 < 0$. Hence $e_2 \leq \frac{1}{2}$. Substituting this back into the equation for e_1 we get $e_1 \leq \frac{1+\frac{1}{2}}{3} = \frac{1}{2}$. \square

Throughout the rest of this chapter we restrict the class of singularities we consider as follows:

Assumption 2.3.3. *Any singularity germ S that appears in this chapter is assumed to be a cyclic quotient singularity with small discrepancy.*

2.4 Log del Pezzo surfaces and small discrepancy

Definition 2.4.1 (?). *Let X be a surface. A -1 cycle $Z = \sum_{D \in S} D \subset X$ is a rationally connected set of curves such that there is a sequence of maps*

$$X = X_0 \longrightarrow X_1 \longrightarrow \cdots \longrightarrow X_n$$

Such that each map is a contraction of a -1 curve $D \in S$ and the image of Z is a nonsingular point.

Lemma 2.4.2. *Let X be a surface having cyclic quotient singularities of small discrepancy, and let $f: Y \rightarrow X$ be the minimal resolution of X . Let $C \subset X$ be a rational curve whose strict transform $\tilde{C} \subset Y$ is smooth. Let $\{E_i\}$ be the exceptional locus of f . Suppose in addition that $\tilde{C} \cdot \sum E_i \geq 2$. Then if $\tilde{C}^2 = -1$ implies $-K_X \cdot C \leq 0$.*

In particular, \tilde{C} is smooth and C either meets at least two singularities of X or meets one singularity with at least branches or has a singular point of C at a singularity of X , then the hypotheses on C are satisfied.

Proof. By the genus formula for $\tilde{C} \subset Y$, as \tilde{C} and Y are both smooth, $K_Y \cdot \tilde{C} =$

–1. If \tilde{C} intersects two distinct exceptional curves E_i, E_j , with discrepancy d_i, d_j respectively, then $K_X \cdot C = f^*(K_X) \cdot \tilde{C} \geq -1 - d_i - d_j \geq 0$, as X has only singularities with small discrepancy. If, on the other hand, \tilde{C} meets only one exceptional curve E_i , but with intersection multiplicity m_i , then $K_X \cdot C = f^*(K_X) \cdot \tilde{C} \geq -1 - m_i d_i \geq 0$. \square

We show next that in fact such rational curves cannot lie on a log del Pezzo. We need a preliminary lemma.

Lemma 2.4.3. *Let X be a log del Pezzo and $f: Y \rightarrow X$ its minimal resolution. Let $C \subset Y$ be a smooth rational curve. If $C^2 \leq -2$ then C is contracted by f to a point of X .*

Proof. We proof this by contradiction. Assume there is a curve C that is not contracted. Then

$$K_X \cdot f(C) = f^*(K_X) \cdot \tilde{C} \geq K_Y \cdot \tilde{C} \geq 0$$

The first inequality follows as $f^*(K_X) - K_Y$ is an effective divisor. The second inequality follows as $K_Y \cdot \tilde{C} = -2 - \tilde{C}^2$. \square

Proposition 2.4.4. *Let X be a log del Pezzo with singularities of small discrepancy and $f: Y \rightarrow X$ its minimal resolution. Consider the following diagram*

$$\begin{array}{ccc} & Y & \\ f \swarrow & & \searrow g \\ X & & Z \end{array}$$

f is the minimal resolution of X and g is a birational morphism to a smooth surface Z . Let $E \subset Y$ be an f -exceptional curve. Then either E is contracted to a smooth point of Z by g , or $g(E)$ is a smooth curve and g_E is an isomorphism.

Proof. Let $E \subset Y$ be any one of the exceptional curves E_i^S over a singularity S of X ; in particular, E is a smooth rational curve with $E^2 \leq -2$. We first show that if $g_*E \subset Z$ is a curve, then it must be a smooth curve.

For contradiction, suppose g_*E is a curve with a singular point P . Let $C_1, \dots, C_s \subset Y$ be the curves that contract to P under g . As these curves are contracted, $C_i^2 \leq -1$. Notice that if $C_i^2 \leq -2$, then $f(C_i)$ is a point of X by Lemma 3.4.3. There are two cases to consider: set-theoretically, either $g^{-1}(P)$ meets E in a single point or in more than one point.

In the case of more than one intersection point, since $g^{-1}(g_*(E))$ is connected, among the curves C_i there must be a shortest chain $C_1 \cup \dots \cup C_r$ with $C_k \cdot E = 0$ for $k = 2, \dots, r-1$, and $(\sum_{i=1}^r C_i) \cdot E = 2$. At least one of the curves $A = C_k$ of the cycle must have $A^2 = -1$, otherwise the whole cycle is contracted to a point R of X , but then $R \in X$ would not be a rational singularity, and so in particular not a cyclic quotient singularity. And of course A cannot meet another -1 -curve C_j with $g(C_j) = P$. Thus A must lie in one of the following configurations:

1. A meets two distinct π -exceptional curves, C_j and $C_{j'}$, both of which have self-intersection ≤ -2 .
2. A meets E in one point and a distinct π -exceptional curves C_j with $C_j^2 \leq -2$.
3. A meets E in two distinct points.

In each of these situations, $C = f_*(A) \subset X$ would be a curve on which K_X is nef, by Lemma 3.4.2, which contradicts X being a log del Pezzosurface. Indeed $A = \tilde{C}$ meets the f -exceptional locus with multiplicity at least 2 in each case.

The argument in the nodal case follows similarly, up to the case division of configurations at which there is an additional case:

We note that if $g^{-1}P$ contains two curve C_i, C_j with $I_Q(C_i, C_j) \geq 2$ then either one of them is a -1 -curve or it cannot occur on the minimal resolution of a log del Pezzo surface. This is because every curve in $\pi^{-1}P$ has negative self-intersection, if its intersection is less than -1 then it would have to be contracted on the map down to X , resulting in a noncyclic quotient singularity. Hence one of them is -1 curve, and this cannot occur as it would contradict Lemma 3.4.2. Hence this cannot occur,

so we have to blow up the point P enough times such that all the intersections are transverse. At this point we have a curve A such that A intersects transversely at least three other curves, $E, C_1, C_2 \dots$ with $C_i \in \pi^{-1}P$. In addition C is the only -1 curve in $\pi^{-1}P$. As Y is constructed from further blowups we split into configurations

1. The strict transform of A , denoted \tilde{A} has $\tilde{A}^2 = -1$.
2. The strict transform of A , denoted \tilde{A} has $\tilde{A}^2 \leq -2$.

In the first case Lemma 3.4.2 this cannot occur on the minimal resolution of a log del Pezzo surface due to the curves $\tilde{E}, \tilde{C}_1, \tilde{C}_2$. In the second case, if none of the intersection points $A \cap E, A \cap C_1, A \cap C_2$ have been blown up then we are left with a noncyclic quotient singularity. Hence one of these points has to be blown up. This results in a -1 -curve intersecting \tilde{A} and another negative curve hence we have a contradiction to Lemma 3.4.2.

For a completely general curve singularity it follows by a combination of the above arguments. □

Proposition 2.4.5. *There is a unique family of non smooth log del Pezzo surfaces S_p , indexed by $p \in \mathbb{N}$, such that given the minimal resolution Y of S_p , Y does not admit a map to \mathbb{F}_i with $i \geq 2$. Here S_p has one $\frac{1}{p}(1, 1)$ singularity.*

Proof. The first case is that Y only admits a map to \mathbb{F}_0 . Then Y must be F_0 , since a blow up of any point of \mathbb{F}_0 also permits a map to \mathbb{F}_1 ; but then $X = Y$ is smooth, contradicting the assumption.

For \mathbb{F}_1 other cases arise. Clearly if we blow up a point on the -1 -curve we get a map to \mathbb{F}_2 . So the only option is a blowup at a smooth point. At this point you get the following toric variety

This results in three adjacent -1 -curves. We now split into cases;

Case 1: Our next blow up is a blow up at a smooth point. This results in DP_6 . We note that on any surface Z which occurs as a blowup at general points of DP_6 has the property that for every -1 curve C there is a map $\pi_C: Z \rightarrow \mathbb{F}_1$ sending C to the negative section B . Hence, in order for X to be nonsingular this involves blowing up a point on a -1 curve. Hence we get the following diagram:

$$\begin{array}{ccc}
 C \subset Z & \xleftarrow{\pi_1} & Z' \\
 \downarrow & & \downarrow \\
 B \subset \mathbb{F}_1 & \xleftarrow{\pi_2} & T \\
 & & \downarrow \\
 & & \mathbb{F}_2
 \end{array}$$

Where the π_i are blow ups of a point on a -1 curve. Hence this case cannot occur.

Case 2: Blowing up a point on the curve which is the pullback of the section B of \mathbb{F}_1 . Once again this results in an obvious map to \mathbb{F}_2 . We note that our surface admits two maps to \mathbb{F}_1 via the symmetry of the surface.

Case 3: Blowing up a general point of the -1 curve which occurred as the strict transform of the fiber. By blowing up $p - 1$ distinct points. This results in an infinite family of log del Pezzo's with a single $\frac{1}{p}(1, 1)$ singularity and potentially A_n singularities. Via the previous arguments any subsequent blowups not on this curve

would induce a map to \mathbb{F}_2 . □

Lemma 2.4.6. *Let X be a log del Pezzo with only singularities of small discrepancy, and let $f: Y \rightarrow X$ be the minimal resolution. We suppose that Y admits a map π to \mathbb{F}_l where $l \geq 2$.*

For a germ S of a singularity of X , denote by $E_i^S \subset Y$ the exceptional curves in the resolution of S . For each singularity S on X :

1. *Every exceptional curve E_i^S is either contracted to a point of \mathbb{F}_l by π , or the pushdown $\pi_* E_i^S \subset \mathbb{F}_l$ is a smooth rational curve with self-intersection one of $-l, 0, l, l+2, 4l$.*
2. *In addition there is always a curve E_j^S not contracted by π for all singularities S .*

Proof. To prove the first statement note that $\pi_* E_i^S$ cannot be a singular curve by Proposition 3.4.4, hence it is a smooth rational curve. The only smooth rational curves on a Hirzebruch Surface \mathbb{F}_l are the curves B , with $B^2 = -l$, F with $F^2 = 0$ and the curves lying inside the linear systems $|lF+B|$, $|(l+1)F+B|$, $|2F|$, $|2(lF+B)|$ and finally $|(l+2)F+B|$. We note that the final case could not arise on \mathbb{F}_l when $l \geq 2$. In this case the curve B is also the image of an exceptional curve from a singularity. Hence any curve in $|(l+2)F+B|$ would intersect B , when counting multiplicities, 2 times. This would be a contradiction to Lemma 3.4.2. A similar argument occurs with $2F$ which is meeting the curve B at a single point with multiplicity 2.

To show that not all the curves E_j^S can be contracted to a point if $l \geq 2$, we go for a proof by contradiction. Assume $l \geq 2$ and every exceptional curve in a singularity S is contracted to a point $P \in \mathbb{F}_l$. Then P lies on a fiber F which intersects the curve B . First we consider $P \notin B$. We have $E_i^S \in \pi^{-1}P$ for all i . Hence we have to blow up several times. However the strict transform of the fiber F , denoted \tilde{F} now has $\tilde{F}^2 \leq -1$. If $\tilde{F}^2 \leq -2$ then it has to be contracted, meaning $\tilde{F}, B \in \{E_i^S\}$ which would be curves not contracted to a point. If $\tilde{F}^2 = -1$, then the only -1

curves in $\pi^{-1}P$ cannot intersect \tilde{F} . This is because after the first blowup we have an exceptional curve E and the fiber \tilde{F} . These both have square -1 . If we blow up the intersection point of \tilde{F} and E then $\tilde{F}^2 \leq -2$, hence we can only blowup general points on E . At this point we have none of the -1 -curves intersecting E . If we blowup no points on E then clearly we are not introducing a singularity so this does not occur. Now finally we note that our curve configuration would contradict Lemma 3.4.2.

□

Remark. *In the case where the length, n , of the singularity is 1 or 2, Lemma 3.4.2 follows via easy toric geometry as any curve joining two singularities is a locally toric configuration. This corresponds to the associated fan being non convex.*

Now we can classify these log del Pezzos in a straightforward way.

Theorem 2.4.7. *Let X be a non-smooth log del Pezzo with only singularities of small discrepancy. Then*

1. *X has either one singularity or two singularities, and if there are two one of the singularities is a $\frac{1}{r_1}(1, 1)$ and the other singularity is a $\frac{1}{r_2}(1, 1)$.*
2. *If X admits no floating -1 -curves then X admits a toric degeneration.*

Proof. Given a log del Pezzo X_0 we start by contracting all floating -1 curves. This gives rise to a log del Pezzo X_1 ; note that X_1 is not \mathbb{P}^2 since the contraction map is an isomorphism in the neighbourhood of any singularity of X_0 . Let $\sigma: Y \rightarrow X_1$ be the minimal resolution of X_1 . We know that there is a map $\pi: Y \rightarrow \mathbb{F}_l$, and we may suppose l is maximal. There is a curve $B \subset \mathbb{F}_l$ with $B^2 = -l$. If $l \geq 2$ then B has to be the image of a σ -exceptional curve E_i inside Y .

We first show that π cannot contract a curve to a point on B . If on the contrary there is a curve contracted to B , then without loss of generality we may assume that it is the exceptional curve of the final blowdown $Y \rightarrow Y_2 \rightarrow \mathbb{F}_l$. In that case, there two

curves C_1, C_2 on Y_2 , both -1 curves, with C_2 being the strict transform of 0 fiber. But then we could instead contract C_2 from Y_2 and get a map to \mathbb{F}_{l+1} , contradicting maximality of l . Hence π is indeed an isomorphism in a neighbourhood of B .

We note that $l \leq 1$ has been classified in Proposition 3.4.5. So we restrict to $l \geq 2$. Now there is a singularity S such that $B \in \{\pi_* E_i^S\}$. Assume first that S is not a $\frac{1}{p}(1,1)$ singularity. Note that there is a curve E_j^S such that $\pi_* E_j^S$ is B . The adjacent (one or two) exceptional curves cannot be contracted (by the argument of the previous paragraph). We suppose there are two adjacent curves $E_{j\pm 1}^S$; the case where E_j^S is at the end of a chain of blowups with only one adjacent exceptional curve works in exactly the same way. Thus each of $\pi_* E_{j\pm 1}^S$ is either a 0 curve (a fiber) or an $l+2$ curve on F_l (by the classification of smooth rational curves on F_l in Lemma ??). Denote these two adjacent curves by C_1 and C_2 respectively. Assume there was another singularity with exceptional curves $\{E_i^{S'}\}_{i=0}^{m_{S'}}$ on Y . Then by Lemma 3.4.6 there would be a curve $E_j^{S'}$ such that $\pi_* E_j^{S'}$ is a curve with self-intersection 0, l , $l+2$. However these curves would necessarily intersect C_1 and C_2 meaning either S' is not distinct from S or there is a -1 -curve in Y connecting two of their curves in the minimal resolution. Hence X has precisely one singularity.

To complete the analysis of this step, suppose S is a $\frac{1}{p}(1,1)$ singularity and that its unique exceptional curve is mapped to the negative section B . Then consider the possibility of there being another singularity S' on X . By Lemma 3.4.6, there is a curve $E_j^{S'}$ such that $A = \pi_* E_j^{S'}$ has self-intersection l or $4l$; it cannot be 0 or $l+2$ as it must not meet B . If S' is not a $\frac{1}{p}(1,1)$ then there is at least one exceptional curve among the $E_k^{S'}$ that is contracted to a point on $A \subset F_l$. However each blowup of a point $Q \in A$ introduces a -1 -curve D which is joined to curve B by another -1 -curve, the birational transform of the fiber through Q . Hence none of these curves $E_k^{S'}$ can be mapped to D , as otherwise it would be adjoined to B by a -1 -curve, contradicting Lemma 3.4.2. Thus any other singularity on X is also of type $\frac{1}{p}(1,1)$ (though possibly for a different p).

Suppose now that there was a third singularity of type $\frac{1}{p}(1,1)$. Once again, its

exceptional curve would have to be sent to a $0, l, l + 2$. Any smooth rational curve on F_l with one of these intersection numbers intersects the curve A . Thus on Y it must either meet the birational transform of A or meet some curve that contacts to A . Once again in the second case it will result in two singularities connected by a -1 -curve. This is a contradiction to small discrepancy.

Thus X has exactly one or two singularities of type $\frac{1}{p}(1, 1)$, and part (1) is complete in the case $l \geq 2$.

For part (2), we first observe that neither of the adjacent curves $E_{j\pm 1}^S$ can map to an $l + 2$ curve, since in that case X will have a floating -1 -curve. This is because $l + 1$ points in general position on the $l + 2$ curve can be cut out as the intersection of the $l + 2$ curve with an l curve.

Because of this we see that the only possibilities for $\pi_*(E_{j\pm 1}^S)$ are two different 0 curves. (Again we suppose there are two adjacent curves; the case of one adjacent curve is the same.) We can then proceed to construct the configuration of all exceptional curves inductively. This means that when a surface of this form is able to be constructed we can obtain it by doing two weighted blowups at a general point of a Hirzebruch surface and then doing a series of non toric blowups on the boundary. The following surface is one example, arising from blowing up two general points of a Hirzebruch surface with weight $(1, i)$ and $(1, n - i)$. This is the picture where the map to the Hirzebruch surface is an isomorphism on an exceptional curve E_i , where $1 < i < n$. Here the red curves indicate -1 -curves and the blue curves indicate curves with positive self-intersection. The blue curve has self-intersection $a_i + 3 - n$. This value is dependent on $n \geq 3$ and the map to the Hirzebruch surface being an isomorphism on a curve E_i with $1 < i < n$. This is because on the Hirzebruch surface \mathbb{F}_{a_i} this curve had self-intersection a_i . The $n - 3$ of our exceptional curves are mapped to points and hence it has self-intersection $a_i - (n - 3)$. In the case that our map is an isomorphism on the curve E_1 or E_n then we have a similar looking configuration except with positive curve now having self-intersection $a_i + 4 - n$ as there is an extra point being blown up however the image of the curve in the Hirze-

bruch surface now is in the linear system $|(l+1)F + B|$. Hence its self-intersection is now $l - (n-3) - 1 = l - n + 4$.

The toric degeneration property now follows. By construction all these surfaces X are Looijenga pairs, and so admit a toric degeneration by [?, Theorem ??]. \square

This leads to the following corollary in which we classify all log del Pezzo surfaces with singularities of small discrepancy, each of which is resolved by a single exceptional curve.

2.5 Examples

Corollary 2.5.1. *Let X be a log del Pezzo surface with small discrepancy and basket $\{\{\frac{1}{p_1}(1,1), \dots, \frac{1}{p_n}(1,1)\}, m\}$ for $n \geq 0$ and $m \geq 0$. Then $n \leq 2$ and moreover*

1. *if $n \leq 1$ then either X is a smooth del Pezzo surface or lies in a cascade over $\mathbb{P}(1,1,k)$ (see [?, Table ??]);*
2. *if $n = 2$ then let c be the highest common factor of p and q and $a = \frac{p}{c}$, $b = \frac{q}{c}$. Then X is isomorphic to a quasismooth weighted hypersurface $X_{a+b} \subset \mathbb{P}(1,1,a,b)$ quotiented out by μ_c acting with weights $(1,1,0,1)$. Conversely any such hypersurface with $p, q \geq 4$ is a log del Pezzo surface with small discrepancy.*

In particular, in the case of two singularities there is no cascade.

The small discrepancy condition is equivalent to the condition that $p_i \geq 4$ for each $i = 1, \dots, n$. For the sake of completeness, we outline the classification result of ? that describes part 1, which also follows independently from Propostion ?? and Theorem 3.4.7.

Proof. With these restrictions on singularities, it fits the criterion for the above theorem. The explicit classification was done in the proof of Theorem 3.4.7. The case of one singularity was done in ?. The only examples of these surfaces with more

than one singularity are constructed by blowing up a Hirzebruch surface in several points along a line and then contracting the two curves. Denote this surface by X . Then X admits a toric degeneration to $(-p_1, -1), (0, 1), (p_2, 1)$. This is $\mathbb{P}(a+b, a, b)$ quotiented out by μ_c acting with weights $(1, 1, 0, 1)$. Taking the v_{a+b} gives us the desired embedding. Note X admits a \mathbb{C}^* action and the degeneration is equivariant with respect to the torus action. We have $-K_X^2 = \frac{4}{p_1} + \frac{4}{p_2}$. Even in cases where $-K_X^2 > 1$ we see that X cannot be blown up while preserving $-K_X$ ample. If X admitted a blow up at a general point P then there is a fiber F such that $P \in F$. Then \tilde{F} is a -1 -curve on the minimal resolution connecting the $-p_1$ curve with the $-p_2$ curve. This is a contradiction. Hence there is only one element in the cascade.

We note that this surface can be seen as a hypersurface of degree $p + q$ inside $\mathbb{P}(1, 1, p, q)$.

□

We now do a more difficult example by classifying the log del Pezzo's with singularities $S_{a,b}$ with resolution E_1, E_2 with $E_1^2 = -a, E_2^2 = -b$. To make sure that this obeys the conditions on the theorem we insist $a, b \neq 2$. We note that the case of $S_{3,3}$ does satisfy the conditions for the theorem. However we are interested in \mathbb{Q} g smoothings and $S_{3,3}$ is not \mathbb{Q} g rigid and admits a partial smoothing to $\frac{1}{6}(1, 1)$ singularity. These were classified above. This is the only one of these singularities which is not \mathbb{Q} Gorenstein rigid. This is a more complicated example of how the above theorem can be used.

Corollary 2.5.2. *Let X be a surface such that the basket is $(\{S_{a_1, b_1}, \dots, S_{a_m, b_m}\}, n)$, with the condition that $a_i, b_i \geq 3$ and we exclude the case $a_i = b_i = 3$. Then there*

is at most one singularities. They fall into a cascade of the form

$$\begin{array}{c}
X_a^0 \xleftarrow{\phi_a^0} X_a^1 \xleftarrow{\phi_a^1} \cdots \xleftarrow{\phi_a^{a-2}} X_a^{a-1} \\
\qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \nwarrow \phi_a^{a-1} \\
\qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad X_1 \xleftarrow{\Phi_1} X_2 \xleftarrow{\Phi_2} X_3 \\
\qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \qquad \nearrow \phi_b^{b-1} \\
X_b^0 \xleftarrow{\phi_b^0} X_b^1 \xleftarrow{\phi_b^1} \cdots \xleftarrow{\phi_b^{b-2}} X_b^{b-1}
\end{array}$$

Proof. Once again by Theorem 3.4.7 there are two heads of the cascade given by the following two surfaces. These correspond to surfaces constructed by blowing up \mathbb{F}_a in b points and \mathbb{F}_b in a points, then contracting the negative curves. We call these surfaces X_a and X_b respectively.

These admits a toric degeneration to $\mathbb{P}(1, b, ab-1)$ and $\mathbb{P}(1, a, ab-1)$ respectively. We only consider the case of X_a as X_b is completely symmetric. We see that the we can smooth it by taking the b th Veronese embedding and getting $\mathbb{P}_{u,v,w,t}(1, 1, ab-1, a)$ with the relation $uw = t^b$. This admits a smoothing giving us the surface lies as $X_{ab} \subset \mathbb{P}(1, 1, ab-1, a)$. We get the following formula for the anticanonical degree of X_a :

$$-K_{X_a}^2 = 8 - b + a \left(1 - \frac{b+1}{ab-1}\right)^2 + b \left(1 - \frac{a+1}{ab-1}\right)^2 - 2 \left(1 - \frac{a+1}{ab-1}\right) \left(1 - \frac{b+1}{ab-1}\right)$$

We will show that this admits a cascade of length $a+2$. The first a terms are easy to describe as we see that these admit a toric degeneration to X_Σ with Σ being the fan with rays $(-1, b)$, $(-1, 0)$, $(a, -1)$, $(a - u, -1)$, where u is the number of blowups. This has an A_{b-1} singularity and an A_{u-1} singularity. Via Cox rings this can be viewed as $\mathbb{C}_{\{x, y, z, t\}}^4$ with a quotient

$$\begin{array}{cccc} x & y & z & t \\ \begin{pmatrix} u & 0 & bu - (ab - 1) & ab - 1 \\ 1 & ab - 1 & b & 0 \end{pmatrix} \end{array}$$

Taking the Veronese embedding of degree u in the variables x, z, t gets us the coordinates z^u, t^u, zt . And to smooth the A_{b-1} singularity we take the b Veronese embedding of the variables x^b, y^b, xy . Once again we can smooth this out. This gives us the surface as complete intersection with weights $\begin{smallmatrix} b & b^2u \\ ab & u \end{smallmatrix}$ inside the toric variety with weights

$$\begin{array}{cccccc} x^b & y^b & z^u & xy & t^u & t^{bu}z \\ \begin{pmatrix} b & 0 & b(bu - (ab - 1)) & 1 & ab - 1 & b^2 \\ 1 & ab - 1 & u & a & 0 & 1 \end{pmatrix} \end{array}$$

The $(a+1)$ st blowup admits a toric degeneration to $(-1, b)$, $(-1, -1)$, $(a, -1)$. The toric degeneration of the $a+2$ 'nd blowup is $(-1, 0)$, $(-a, -1-a)$, $(-1, -1-a)$, $(b, ab-1)$. We note that this surface still has a boundary of a curve $C \in -K_X$. This strict transform $\tilde{C} \subset Y$ has self-intersection 0 as it started of as an $a+2$ curve and has been blown up $a+2$ times. Hence X admits a degeneration as it is a Looijenga pair. To see the cascade result we note that if you blow up the surface X_a times at points $P_1 \dots P_a$. To each of these points there is a unique fiber going through it F_i . The strict transform of these fibers after blowing up is a -1 -curve going through the $-a$ curve. Hence after blowing X_a and X_b respectively a and b times we get a surface

which has as a boundary three curves with self-intersection $0, -a, -b$ and in both cases you have your a and your b curves have a and b minus one curves intersecting them respectively. Hence they are isomorphic.

We note that we have made in the above calculations no effort to show that the elements in the cascade are log del Pezzo surfaces. However it is not hard to show, assume we are blowing up $a+2$ points giving surface X_3 . This has minimal resolution Y_3 . The class group of Y_3 is generated by the curves $D_1, D_2, D_3, D_4, E_1^0, \dots, E_b^0, E_1^1, \dots, E_{a+2}^1$. Here the D_i for a cycle such that $\sum D_i \in |-K_{Y_3}|$. These have self-intersections $-a, -b, -1, -1$ respectively. Here D_3 was a curve of degree a on \mathbb{F}_a blown up $a+1$ times and D_4 was a fiber on which a point has been blown up. The E_i^0 are -1 -curves intersecting the $-b$ curve. The E_i^1 are floating -1 -curves. We wish to show $-K_{X_3}$ is ample. We note that showing $-K_{X_3} \cdot C > 0$ for all C generating the class group would suffice. We note that the curves D_1, D_2 are contracted when sent to X_3 . We note that $-K_{X_3} \cdot E_i^0 = -K_{X_a} \cdot E_i^0$ as we are blowing up points not on these curves. Then $-K_{X_3} \cdot E_i^0 = 1$ as these are floating -1 -curves. Finally to see that $-K_{X_3} \cdot D_3 > 0$ we note that, when pushed forwards to X_3 , it only goes through the one singularity on X_3 with multiplicity -1 . This is because on Y_3 it is only intersecting the $-a$ curve transversely. Hence $-K_{X_3} \cdot D_3 = 1 + d_a$ where d_a is the discrepancy of the $-a$ curve. Via log terminality we have $d_a > -1$. Hence the product is greater than 0. The argument for the curve is exactly the same with d_a replaced with d_b . From this we see X_3 is a log del Pezzo, hence every surface in the cascade is a log del Pezzo surface. \square

This structure of the cascade can be put in more general terms.

2.6 Cascades

Theorem 2.6.1. *Given a singularity with small discrepancy such that the minimal resolution is a_1, \dots, a_n , there are a finite number of basic surfaces classified in the previous theorem. Let X_i be the surface constructed from X_{a_i} . If $i \neq 1, n$ then this*

admits a cascade of length $a_i + 3 - n$, if $i = 1, n$ then the cascade is of length $a_i + 4 - n$.

In addition we can describe the shape of the cascade. In the case when the singularities are of the form $\frac{1}{p}(1, 1)$ the cascades have been classified by ? and the above example. We explained the case of the singularity of length 2 above. In the case of the singularity having length 3, then the cascade looks like:

$$\begin{array}{ccccccc}
X_1^0 & \xleftarrow{\phi_1^1} & X_1^1 & \xleftarrow{\phi_1^2} & \dots & \xleftarrow{\phi_1^{a_1-2}} & X_1^{a_1-1} \\
& & & & & & \nwarrow \phi_1^{a_1-1} \\
X_2^0 & \xleftarrow{\phi_2^1} & X_2^1 & \xleftarrow{\phi_2^2} & \dots & \xleftarrow{\phi_2^{a_2-1}} & X_2^{a_2-1} \xleftarrow{\phi_2^{a_2}} X_1 \xleftarrow{\Phi_1} X_2 \xleftarrow{\Phi_2} X_3 \\
& & & & & & \nearrow \phi_3^{a_3-1} \\
X_3^0 & \xleftarrow{\phi_3^1} & X_3^1 & \xleftarrow{\phi_3^2} & \dots & \xleftarrow{\phi_3^{a_3-2}} & X_3^{a_3-1}
\end{array}$$

For any singularity of length greater than 3, then a basic surface either falls into a cascade of the above form or it lies in a straight series.

Proof. Given a singularity S of small discrepancy with length $m > 1$. Then a basic surface X with singularity S has minimal resolution Y . The surface Y is constructed by taking a Hirzebruch surface \mathbb{F}_{a_i} picking two points P_1, P_2 and blowing them up k_1 and k_2 times, this gives rise to an intermediate surface Z and then X is constructed by doing further blow ups. We can assume $k_1 \leq k_2$ and this gives the relations that either $k_1 = k_2 = 0$ and $m \in \{1, 2, 3\}$ or $k_1 = 0$ and $k_1 = m - 2$ or $k_1 + k_2 = m - 3$. These cases arise by considering the case where the strict transform of both/ one/ none of the fibers are exceptional curves. The case where no fiber becomes an exceptional curve has been classified in Example ?? and we will not mention it further.

We note that k_1 and k_2 should not be viewed as invariant of the surface X but an

invariant of the given map to \mathbb{F}_{a_i} :

$$X \xleftarrow{f} Y \xrightarrow{\pi} \mathbb{F}_{a_i}$$

We now note that by construction in the case where the strict transform of both fibers are exceptional curves we get a curve C on Y with self-intersection $a_i - k_1 - k_2$. Via construction C was a toric curve and $f_*(C) \in |-K_X|$. We have that the class group of X is generated by C and D_i where D_i are the curves arising from the non toric blowups of Y . This implies that the cascade of X is of length $L = a_i - k_1 - k_2$ as blowups in general position do not affect the $-K_X \cdot D_i$ and when we blow up $a_i - k_1 - k_2 + 1$ times $K_X^2 \leq 0$ via the small discrepancy condition. If $L < 0$ then this surface is not a log del Pezzo surface.

In the case where one of the fibers is not exceptional, so $k_2 = 0$, we have that the class group is generated by the same D_i , the fiber class F and a final curve C . Here $-K_X = C + F$ and $F^2 = 0$, $C^2 = a_i - k_1$. This surface admits a cascade of length $L = a_i - k_1 + 2$. This is because, we only need to calculate the intersections on the subgroup generated by C and F . If we blowup L times we can assume that we blew up one point on the fiber F and $a_i - k_1 + 1$ points on the curve C . After this process the strict transform of both these curves would have self-intersection -1 . As these are both on through a singularity with multiplicity one we see that $-K_X$ has positive intersection with these curves. If we blow up one more time we can assume all $L + 1$ points lie on a curve in the class $|C + F|$ this has self-intersection L and hence after all these blowups would be a -1 curve intersecting the singularity twice. This would not be a log del Pezzo surface via small discrepancy.

We now wish to explore the birational relationships between these surfaces. The first stage is to show that the only possible -1 curves on any surface in the cascade arise from the class $|B + a_i F|$ on the Hirzebruch surface \mathbb{F}_{a_i} . To show this we note that it is impossible for any curve that intersects $|B|$ to end up being a floating curve as it will always intersect the curve B . So any floating curve C lies in the class $n|B + a_i F|$. To show that $n = 1$ we compute the self intersection of these curves. If $n = 2$ then

the smallest possible self intersection of a curve not going through the singularity is $4a_i - k_1 - k_2 - 4$ if there is two exceptional fibers and $4a_i - k_1 - 2$ if there is only one. As in the first case $L = a_i - k_1 - k_2$ as $a_i \geq 2$ we have $4a_i - k_1 - k_2 - 4 > L$ so we cannot blow up enough to make this a -1 curve. In the second case $L = a_i - k_1 + 2$ so once again as $a_i \geq 2$ we cannot blow up enough to make it a -1 curve. As n increases the size of the self intersection increases and hence they can never occur as floating -1 curves.

Now we explicitly state how the cascade structure occurs. We note that out of the exceptional curves $E_i \subset Y$ only the curves that arose as part of the original k_1 and k_2 blowups can be intersected by curves in the class $|B + a_i F|$ as otherwise they would have to intersect the fiber with multiplicity greater than 1. Label these curves S_1, \dots, S_{k_1} and T_1, \dots, T_{k_2} with S_1 and T_1 being the strict transforms of the fibers. Hence any potential floating curve intersects a -1 curve coming out of a curve S_i and a -1 curve coming out of T_j . We now denote by $C_{i,j}$ the curve intersecting a -1 curve coming from S_i and a -1 curve coming from T_j . Then in the case of both fibers becoming exceptional curves $C_{i,j}^2 = L - 4 + i + j$ so in order for it to become a -1 curve it needs to be blown up in $L - 3 + i + j$ points. However as the length of the cascade is L this implies $i + j \leq 3$. So $\{(i, j)\} = \{(1, 1), (1, 2), (2, 1)\}$. We now go on a case by case analysis:

Case 1: We start with $(i, j) = (1, 1)$. It takes $L - 1$ blowups for this to become a -1 curve. Denoting the number of -1 curves intersecting S_1 and T_1 by s, t , we label these curves D_u^S and D_v^T respectively. We have st possible curves which would give rise to a -1 curve after $L - 1$ blowups. We denote by $C_{u,v}$ the curve intersecting D_u^S and D_v^T . These curves originally lay in $|B + a_i F|$ so on the Hirzebruch surface they intersected b times. By repeating the same calculation on this on Y blown up $L - 1$ times, we see that $C_{u,v}$ intersects $C_{u',v'}$ if and only if $u \neq u'$ and $v \neq v'$. So fixing $C_{u,v}$ we get the following curve configuration

Hence if we choose a floating -1 curve $C_{u,v}$ to contract the only remaining floating curves are $C_{\alpha,\beta}$ and $C_{\alpha,v}$ where $\alpha \in \{1, \dots, s\}$ and $\beta \in \{1, \dots, t\}$. When the

second floating curve is contracted this uniquely defines whether we are iterating over s or over t . So after two contractions the cascade is uniquely defined. To see where it ends up we note that a basic surface is uniquely defined by the number of -1 curves coming out of each curve on the boundary. Picking one of these chains of leads to either s blowdowns or t blowdowns. These cases behave symmetrically, so focusing on the case of s blowdowns we get a curve $E_1 \subset Y$ with self intersection a and no -1 curves coming out of it. So it is not unreasonable to hope that this admits a map to \mathbb{F}_{a_1} . To show this we introduce even more notation. We note that we can start by contracting all -1 curves intersecting the exceptional curves. We previously had 2 fibers $F_1 = [f_1, \dots, f_{m_1}]$ and $F_2 = [g_1, \dots, g_{m_2}]$ and after purely toric contractions F_1 can be mapped to $[-1, -2, -2 \dots -2, -1]$ with length k_1 , the analogous statement holds for F_2 . We note that the curve E_1 is still in the fiber $[-1, -2, -2, \dots -2, -1]$. After our new series of contractions we now have a curve configuration $[-a_1, f_2, f_3 \dots f_{m_1}, L-1-a_i, g_1, \dots, g_{m_2}] = [-a_1, f_1, f_2 \dots f_{m_1}, -k_1 - k_2 - 1, g_1, \dots, g_{m_2}]$. We can repeat our toric contractions to contract this too $[-a_1, -2, \dots -2, -1, -k_1 - k_2 + 1, -1, -2, \dots, -2, -1]$, at this point as the number of -2 curves on the left is k_1 and the number of -2 curves on the right is k_2 we see that this curve configuration can be constructed by blowing up the configuration $[-a_1, 0]$ in the following way:

$$\begin{array}{c}
[-a_1, 0] \\
\uparrow \\
[-a_1, -1, -1] \\
\uparrow \\
[-a_1, -2, -1, -2] \\
\uparrow \\
[-a_1, -2, \dots, -2, -k_1 - 1, -1] \\
\uparrow \\
[-a_1, -2, \dots, -k_1 - k_2 - 1, -2, -2 \dots -2]
\end{array}$$

So in particular this arises from a basic surface with $k_2 = 0$, $k_1 = 1$ and the strict transform of only one becoming an exceptional curve. This concludes the first case.

Case 2: The second case is $(i, j) = (1, 2)$. We do not spell this out in the same level of detail. Replicating the above arguments we see that we now get exactly the same curve configuration as in Figure 2 except now connecting the curves E_1^S to E_2^T . So once again this leads to a set of two branching contractions. Once again this leads to a basic surface with $k_1 = 1$ and $k_2 = 0$. However this time there are two fibers that are now exceptional curves on Y . This proof follows from exactly the same logic as above.

Case 3: The final case is $(i, j) = (2, 1)$. This is symmetrical to case 2.

A crucial point in this proof is that each case behave independently of the others as two floating curves don't intersect each other only if they lie in the same case.

We note that if there are no -1 curves coming out of the curves E_1^S and E_1^T then the cascade is a straight line as the above discussion is entirely predicated on their existence. This concludes the cascade for basic surfaces of this type.

We make a quick mention of what happens in the case where there is only one exceptional fiber. These surfaces all start by blowing up a point k times. Label the exceptional curves that arose from blowing up this point E_k, \dots, E_1 and we denote the strict transform of the fiber by E_0 . Once again $L = a_1 - k + 2$ and we have curves with self intersection $a_1 - i - 1$ intersecting the -1 curves coming out of E_i . To get a -1 curve we need $a_1 - i - 1 < L = a_1 - k + 2$ giving $k - i < 3$ so $i \in \{k, k-1, k-2\}$. After $a_1 - k$ blowups we get a straight chain of blowdowns arising from floating -1 curves intersecting -1 curves coming out of E_k . After $a_1 - k + 1$ blowups we also get -1 curves intersecting the fiber E_{k-1} . These curves, pre blowups, intersect the potential floating curves arising from E_k $a_1 - k - 1$? times. We have then blown up $a_1 - k + 1$ points

□

Remark. The surfaces $X_{a_i}^{k_1+k_2}$ always exist but may not always have $-K_X$ being ample. This depends purely on the values a_i, k_1, k_2 .

Corollary 2.6.2. Let S be a singularity with small discrepancy, $-a_1, \dots, -a_n$ be the self-intersection of the resolutions. Then if $n \geq \max(a_i) + 5$. Then there exists no log del Pezzo with only singularities of type S .

Remark. It is fully possible for both X_1 and X_2 to exist but one of the $X_{a_i}^0$ to not exist. For example consider a singularity with resolution $-3, -8, -2, -2, -2, -2, -2, -2, -3$. There will be a surface X such that the resolution will have a map to \mathbb{F}_8 but there will be no surface with a map from its resolution to \mathbb{F}_3 .

2.7 Outside of the small discrepancy

If you consider singularities of the type $\frac{1}{p}(1, 1)$ we note that if $p \geq 7$ then a $\frac{1}{p}(1, 1)$ singularity cannot be joined to any other $\frac{1}{p}(1, 1)$ singularity by a -1 curve. Hence a similar analysis to Theorem 3.4.7 gives us the bound that there cannot be a log del Pezzo surface X with singularities $\frac{1}{p_1}(1, 1), \dots, \frac{1}{p_n}(1, 1)$ and $p_1 \geq 7$ and more than 2 different singularities.

However when we enter the case where $p_1 < 7$ you can get surfaces with many more singularities. For instance consider the surface X with the following minimal

resolution:

This has $h^0(-K_X) \neq 0$, $-K_X^2 = \frac{3}{5}$, six $\frac{1}{3}(1, 1)$ singularities and two $\frac{1}{5}(1, 1)$ singularities. In addition it admits no normal toric degeneration, as it is a complexity one surface and hence any degeneration would have to be equivariant. We can construct this as a toric complete intersection via cox rings and we see that it lies as a complete

intersection in the toric variety given by the GIT quotient

$$\begin{array}{cccccccccc}
 T_1 & T_2 & T_3 & T_4 & T_5 & T_6 & T_7 & T_8 & T_9 & T_{10} & T_{11} \\
 \left(\begin{array}{cccccccccc}
 0 & 3 & -6 & -2 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
 0 & 2 & -4 & -1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
 1 & -2 & 3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
 0 & 3 & -6 & 0 & 0 & 0 & -2 & 1 & 0 & 0 & 0 \\
 0 & 2 & -4 & 0 & 0 & 0 & -1 & 0 & 1 & 0 & 0 \\
 0 & -3 & 7 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\
 0 & 1 & -2 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1
 \end{array} \right)
 \end{array}$$

with the equations

$$T_1 T_2^2 T_3 + T_4 T_5^2 T_6 + T_7 T_8^2 T_9$$

$$T_1 T_2^2 T_3 + T_4 T_5^2 T_6 + \lambda T_{10} T_{11}$$

We note that there are also surfaces which admit toric degenerations with the same numerics

Figure 2.1: Example of surface.

Figure 2.2: Figure 2. This is currently not correct, fix the intersection

Chapter 3

Complexity One log Del Pezzo Surfaces

3.1 Introduction

3.2 Introduction

All varieties we consider are normal and projective. Here we give an algorithm to classify Log Del Pezzos admitting a \mathbb{C}^\times action with only log terminal singularities. A variety X of dimension n which admits a torus action of dimension $n - k$ is referred to as complexity k . Here complexity 0 is the study of purely toric varieties, and complexity n is the study of varieties with no possible torus action. This provides essentially a way of grading the difficulty of your problem. Significant progress has been made on this problem before: Süss ? classifies log del Pezzo surfaces admitting said action with Picard rank one and index less than 3. Huggenberger ? classifies the anticanonical complex of the Cox ring of log del Pezzo surfaces with index 1, this classification was later finished by Ilten, Mishna and Trainor ? with a view towards higher dimension. This was achieved by looking at polarised complexity one log del Pezzo surfaces. We will show their work fits into our algorithm.

3.3 Polyhedral divisors

Recall that a toric variety is a normal variety of dimension n containing a dense torus $(\mathbb{C}^*)^n$ with the natural action extending to the variety, there is a one to one correspondence between these varieties and fans inside a lattice $N \cong \mathbb{Z}^n$ upto $\text{GL}_2(\mathbb{Z})$, ?. Altman et.al ? establish a similar correspondence for varieties with $T = (\mathbb{C}^*)^{n-k}$ actions where $k \leq n$. We say that this is a torus action of complexity k . They introduce the notion of a polyhedral divisor to recover some of the geometry that a fan encodes in the toric case. In general this applies for any complexity, however the behaviour is easiest to describe in the toric case, then complexity one until you reach the full general case.

Given X , a variety with dimension n admitting of the torus $T = (\mathbb{C}^*)^{n-1}$ action, we can take a Chow quotient Y of X by T , essentially a GIT quotient followed by normalisation. We see that Y will be a variety of dimension k , we can resolve this map to \tilde{X} getting the following diagram

$$\begin{array}{ccc} X & \longleftarrow & \tilde{X} \\ & \searrow & \downarrow \\ & & Y \end{array}$$

Here $Y \cong C$ is a normal curve. In this thesis we will primarily be interested in the case where $C \cong \mathbb{P}^1$. We start by introducing the notion of a tail cone of a given polyhedral cone. This is given F a polyhedral subdivision such that the tail cone δ is the set of $v \in N$ such that F_i is invariant under the translation, i.e $\delta = \{v \mid v(F) \text{ subset } F\}$.

Definition 3.3.1. *Let C be a nonsingular curve then we define a polyhedral divisor to be the pair $(\mathcal{D} = \sum_{i=1}^k F_i \otimes P_i, \delta)$ where*

- $P_i \in C$ are divisors on C
- F_i is a polyhedron contained in $N_{\mathbb{Q}} \cong \mathbb{Q}^{n-1}$ and all F_i have tail cone $\delta \subset N$.
We allow the cone F_i to be \emptyset .

Given an element $v \in M$, the dual lattice of N , and the polyhedral divisor \mathcal{D} we define

$$\mathcal{D}(v) = \sum_{u \in F_i} \min \langle u, v \rangle P_i$$

This is defined as a divisor on the following curve

$$Y_{\mathcal{D}} = C - \{P_j\}_j \text{ where } F_j = \emptyset$$

This defines a divisor on a subset of C . We insist that \mathcal{D} satisfies the following conditions:

1. $\mathcal{D}(u)$ is Cartier for all $u \in \delta^{\vee}$
2. $\mathcal{D}(u)$ is semiample for all $u \in \delta^{\vee}$
3. $\mathcal{D}(u)$ is big for all u in the relative interior of δ^{\vee}

This is to ensure that it gives an n -dimensional variety, and to ensure that it is separated ?.

We can now calculate the associated affine varieties X and \tilde{X} by taking respectively $\text{Spec}/\text{RelSpec}_C$ of the graded ring

$$\bigoplus_{v \in \delta^{\vee}} \mathcal{O}_{Y_{\mathcal{D}}}(\mathcal{D}(v))$$

This gives us an affine variety with $T = \text{Spec } \mathbb{C}[M]$ acting by torus action. Analogous to the toric case, if $F_i \subset F_j$ is a face then we have

$$\bigoplus_{v \in \delta^{\vee}} \mathcal{O}_{Y_{\mathcal{D}}}(\mathcal{D}_{F_j}(v)) \subset \bigoplus_{v \in \delta^{\vee}} \mathcal{O}_{Y_{\mathcal{D}}}(\mathcal{D}_{F_i}(v))$$

This corresponds to an inclusion of schemes. We make the following comment that taking a divisor

$$\mathcal{D} = \sum_{i=1}^n F_i \otimes P_i + \emptyset \otimes P_{n+1}$$

is the same as taking the divisors

$$\mathcal{D}_i = F_i \otimes P_i + \sum_{j=1, j \neq i} \emptyset \otimes P_j$$

and then glueing these affine varieties together along the affine patch defined by $C - P_i - P_j$ for all P_i, P_j . We say that if the tail cone of a polyhedral divisor \mathcal{D} is non zero and there is no point P such that $\mathcal{D}|_P = \emptyset$ then \mathcal{D} is marked. The variety \tilde{X} is defined to be the variety such that the cone is not marked.

We now introduce the notion of a polyhedral fan. Consider a collection of polyhedral divisors $\mathcal{S} = \{\mathcal{D}_i\}$ such that the tail cones form a fan in the sense of toric geometry, we call this the tail fan. Given $\mathcal{S} \ni \mathcal{D}_i = \sum \sigma_j^i \otimes P_j$ then we can make the divisor $\mathcal{D} = \sum \tau_j \otimes P_j$ where τ_j a face of each cone corresponding to a face of the tail cone. If $\mathcal{D} \in \mathcal{S}$ for all possible faces of all the tail cone, then this is a polyhedral fan. As this is stated above this makes no mention of how this behaves with respect to a divisor $\mathcal{D} = \sum \sigma_i \otimes P_i + \emptyset \otimes P$. To do this we add that if given a face of the tail fan δ there is associated polyhedral divisor $\mathcal{D} = \sum \sigma_i \otimes P_i$ with δ as its tail cone. We then insist that if a cone in the tail fan is not marked then every face of the cone is also not marked. If the collection \mathcal{S} satisfies these conditions then we call it a polyhedral fan.

Given a complexity one projective variety X over a curve C this corresponds to a polyhedral fan with the tail fan spanning N . Analagously to the case in cones, the variety \tilde{X} is defined to be the complexity one variety with the same tail fan and polyhedral divisors however every cone is not marked. The action of the $(\mathbb{C}^\times)^{n-1}$ on \tilde{X} corresponds to a fibration over C with general fiber X_t equal to the toric variety defined by the tail fan. The degenerate fibers are then described by the polyhedral fans.

In the case of surfaces of complexity one we often use the notation of fansy divisors as set out in ?. This follows the key notion that in the case of $n = 2$ and $k = 1$ we have that every tail fan is either 0 , $\mathbb{Z}_{\geq 0}$ or $\mathbb{Z}_{\leq 0}$. We have n subdivisions of $N \cong \mathbb{Z}$, these should be viewed as the polyhedral divisors over these n points. Note that if we have a closed interval in any of subdivisions this will have tail fan zero and these give rise to a cyclic quotient singularity, with a nice torus quotient, i.e the map to \tilde{X} is a contraction to a point. It is the intervals $[a_1, \infty)$ which provide difficulty, if as polyhedral divisors these are all of the form

$$\mathcal{D}_i = [a_i, \infty) \otimes P_i + \sum_{\substack{j=1 \\ j \neq i}}^n \emptyset \otimes P_j$$

Change this paragraph Then this gives rise to a nice quotient map down base curve with respect to the torus action, i.e the map to \tilde{X} is a local isomorphism. If this is not the case however, then we are left with a bad quotient. In the surface case, there are the only two cases that can occur. In the language of fansy divisors we say if we mean the latter case we denote it with \mathbb{Q}^+ , if we mean the other the earlier case, we do not denote it at all. In this way fansy divisor uniquely specify polyhedral fans.

3.4 Example

Example 3.4.1. The first is the polyhedral divisor given by the unmarked polyhedral divisor $[0, 1] \otimes P_0$ over $Y = \mathbb{P}^1$. The tail cone δ is equal to 0 . We will show how we can construct from this an affine variety X . We denote the polyhedral divisor by \mathcal{D} . So the dual of the tail cone $\hat{\delta}$ is the lattice M itself. Given an element $m > 0$ of M we have $\mathcal{D}(m) = -mP_0$ as the minimum value is obtained on -1 . If $m < 0$ we get $\mathcal{D}(m) = mP_0$ as the minimum is attained on 1 . Finally if $n = 0$ we get $\mathcal{D}(m) = 0$ as a divisor on \mathbb{A}^1 as the function is 0 everywhere.

Hence we have the M graded ring

$$\bigoplus_{m \in M} \mathcal{O}_{\mathbb{A}^1}(-|m|P)$$

In degree 0 the ring is generated by the constant function on \mathbb{A}^1 which we denote x and the function y which is zero at the origin. We note that the function 1 in degree 0 is the multiplicative identity of our ring. In degree one every element is of the form $f(a_0x + a_1y + a_2y^2 + \dots a_ny^n)$, here f is the same function on \mathbb{A}^1 as y but now in degree 1. Every element of degree $m > 0$ is of the form $f^m(a_0x + a_1y + a_2y^2 + \dots a_ny^n)$. Hence this ring is generated in degree 1. The calculation on the ring graded in negative degree is exactly the same, except with a function g . We note that $fg = y^2$ as f and g are both equal to y as functions on \mathbb{A}^1 . We finally discuss the function x . Given a function $F \in \mathbb{C}(X)$, then $F = \sum F_i \chi^{m_i}$, here the F_i are functions on the curve Y and χ^{m_i} are monomials in the lattice M . By construction the function $x = \mathbb{1}_Y \chi^0$, hence x is the constant function on the variety. Hence we get the ring $\mathbb{C}[f, g, y]/(fg = y^2)$, so an A_1 singularity.

We can more generally describe what occurs with polyhedral divisors of the form $[\frac{a}{b}, \frac{c}{d}] \otimes P_0$ with $\frac{a}{b} < \frac{c}{d}$. We note that the tail cone δ is always 0 and so the dual tail cone is all of M . From the definitions we get the ring $R = \bigoplus_{m \in M} R_m \chi^m$ where

$$R_m = \begin{cases} \mathcal{O}_{\mathbb{A}^1_z}(\frac{ma}{b}P) & \text{if } m \geq 0 \\ \mathcal{O}_{\mathbb{A}^1_z}(\frac{mc}{d}P) & \text{if } m \leq 0 \end{cases}$$

We can associate the monomial $z^u \chi^v$ with the lattice point (u, v) inside a two dimensional monomial lattice. This gives rise to a cone σ . The set of monomials with poles of order at worst $\frac{a}{b}$ gives rise to the vector $(a, -b)$. Similarly the other side of the graded ring gives rise to the vector $(-c, d)$. These are boundaries σ , this means that as toric variety they can be described as the cone $(a, b), (c, d)$ inside the lattice $N \cong \mathbb{Z}^2$ with torus action corresponding to $(1, 0)$. Hence we get a toric variety of

the form $\frac{1}{r}(\alpha, \beta)$ where $r = bc - ad$ and α and β are generators of the kernel of the matrix M modulo r where

$$M = \begin{pmatrix} c & a \\ d & b \end{pmatrix}$$

Example 3.4.2. We now show how this behaves in the case of a divisor with tail cone $\delta = [0, \infty)$. Consider the divisor $\mathcal{D} = [\frac{1}{2}, \infty) \otimes P_0 + [\frac{1}{2}, \infty) \otimes P_1 + [\frac{-1}{2}, \infty) \otimes P_2$ over \mathbb{P}^1 with coordinates x_1, x_2 . Here the varieties X and \tilde{X} are different. To start with, we look at how to construct X . For simplicity we assume $P_0 = (1; 0)$, $P_1 = (1; 1)$ and $P_2 = (0; 1)$.

The tail cone is $\delta = [0, \infty)$ so $\hat{\delta} = [0, \infty)$. By calculating $\mathcal{D}(m)$ we get the following ring

$$\bigoplus_{m \in M|_{\geq 0}} \mathcal{O}_{\mathbb{P}^1} \left(\frac{m}{2}P_0 + \frac{m}{2}P_1 + \frac{-m}{2}P_2 \right)$$

Once again in degree 0 we get the constant function. In degree one we get no functions. In degree 2 we get 2 functions $\frac{x_2}{x_1}\chi^2$ and $\frac{x_2}{x_1-x_2}\chi^2$ denote these u and v . In degree 3 we get the function $\frac{x_2^2}{x_1(x_1-x_2)}\chi^3$ denote this by w . We then have the relations $w^2 = uv(v - u)$. This gives rise to a D_4 singularity.

To calculate \tilde{X} we do all these calculations as relative spec. In particular this means we can our above graded ring with the following three graded rings

$$\bigoplus_{m \in M|_{\geq 0}} \mathcal{O}_{(\mathbb{P}^1 - P_i - P_j)} \left(\frac{m}{2}P_0 + \frac{m}{2}P_1 + \frac{-m}{2}P_2 \right)$$

For all choices of i and j . We then glue together on the intersection. Calculating in the case $i = 1$ and $j = 2$. We have

$$\bigoplus_{m \in M|_{\geq 0}} \mathcal{O}_{(\mathbb{P}^1 - P_1 - P_2)} \left(\frac{m}{2}P_0 + \frac{m}{2}P_1 + \frac{-m}{2}P_2 \right) \cong \bigoplus_{m \in M|_{\geq 0}} \mathcal{O}_{(\mathbb{A}^1 - P_1)} \left(\frac{m}{2}P_0 \right)$$

This gives us the ring $\mathbb{C}[x, \frac{1}{x+1}, \frac{1}{x}\chi^2, \chi^1] = \mathbb{C}[u, v, w, t]/[v(u+1) = 1, uw = t^2]$. Hence this is an A_1 singularity. The calculations on the other 3 patches are the same, so

we have taken the partial resolution of the D_4 singularity by extracting the trivalent curve.

Example 3.4.3. Consider the following polyhedral fan with marking \mathbb{Q}^\pm

We now go through each polyhedral divisor and calculate the associated rings. There are three polyhedral divisors contained inside this polyhedral fan which are one dimensional cones. There are three polyhedral divisors which correspond to two dimensional cones.

- a) The unmarked polyhedron $[-1, 1]$
- b) The marked cone $1 \otimes P_0 + \frac{1}{2} \otimes P_1 + \frac{-1}{2} \otimes P_\infty$ with tail cone $[0, \infty)$.
- c) The marked cone $-1 \otimes P_0 + \frac{1}{2} \otimes P_1 + \frac{-1}{2} \otimes P_\infty$ with tail cone $(-\infty, 0]$.

In case a the tail cone δ is equal to 0. We denote the polyhedral divisor by \mathcal{D} . So the dual of the tail cone $\hat{\delta}$ is the lattice M itself. Given an element $m > 0$ of M we have $\mathcal{D}(m) = -mP_0$. If $m < 0$ we get $\mathcal{D}(m) = mP_0$ and if $n = 0$ we get $\mathcal{D}(m) = 0$

as a divisor on \mathbb{A}^1 .

Hence we have the M graded ring

$$\bigoplus_{m \in M} \mathcal{O}_{\mathbb{A}^1}(-|m|P)$$

In degree 0 the ring is generated by the constant function x and the function y which is zero at the origin. We note that the function 1 in degree 0 is the multiplicative identity of our ring. In degree one every element is of the form $f(a_0x + a_1y + a_2y^2 + \dots a_ny^n)$, here f is the same function as y but now in degree 1. Every element of degree $m > 0$ is of the form $f^m(a_0x + a_1y + a_2y^2 + \dots a_ny^n)$. Hence this is generated in degree 1. The calculation on the ring graded in negative degree is exactly the same. Hence we get the ring $\mathbb{C}[f, g, y]/(fg = y^2)$, so an A_1 singularity.

In case a the tail cone δ is equal to $[0, \infty)$. We denote the polyhedral divisor by \mathcal{D} . So the dual of the tail cone $\hat{\delta}$ is $[0, \infty) \subset M$. Given an element $m \geq 0$ of M we have $\mathcal{D}(m) = mP_0 + \frac{m}{2}P_1 + \frac{-m}{2}P_2$.

Hence we have the M graded ring

$$\bigoplus_{m \in M|_{\geq 0}} \mathcal{O}_{\mathbb{P}^1} \left(mP_0 + \frac{m}{2}P_1 + \frac{-m}{2}P_2 \right) \cong \bigoplus_{m \in M|_{\geq 0}} \mathcal{O}_{\mathbb{P}^1} \left(\frac{m}{2}P_1 + \frac{m}{2}P_2 \right)$$

Here the isomorphism follows via linear equivalence of divisors on \mathbb{P}^1 .

In degree 0 we just get the constant function. In degree 1, once again it is only the constant function, denoted this by x . In degree 2 we have the function with a pole at P_1 and a zero at P_2 , denote this by f and the function $g = \frac{1}{f}$. This generates the ring hence we have $\mathbb{C}[x, f, g]/(fg = x^4)$, so an A_3 singularity.

Case c is exactly the same as case b but with the grading negative instead of positive. So it is also an A_3 singularity.

We finish by discussing the unmarked polyhedral divisors

A) The unmarked cone $-1 \otimes P_0$

B) The unmarked cone $1 \otimes P_0$

C) The unmarked cone $\frac{1}{2} \otimes P_1$

D) The unmarked cone $-\frac{1}{2} \otimes P_2$

In all case the tail cone δ is equal to 0. In case *A* have the following ring graded by M

$$\bigoplus_{m \in M} \mathcal{O}_{\mathbb{A}^1}(-mP) \cong \mathbb{C}[x, y, z]/(yz = 1)$$

Here x is of degree 0, y is of degree 1 and z is of degree -1 . Case *B* is symmetrical to case *A*.

Cases *C* and *D* are also symmetrical, and give rise to the rings $\mathbb{C}[x, y_1, y_2, z_1, z_2]$ with relations induced by the second veronese embedding of $C[x, y, z]/(yz = 1)$.

To see all the glueings we have the following

We explicitly describe the maps 1) and 2). To see map 1) the base is

$$\bigoplus_{m \in M|_{\leq 0}} \mathcal{O}_{\mathbb{P}^1} \left(-mP_0 + \frac{-m}{2}P_1 + \frac{m}{2}P_2 \right)$$

and the image is

$$\bigoplus_{m \in M} \mathcal{O}_{\mathbb{A}^1}(-mP_0)$$

There is clearly an inclusion of rings on each level of the negative grading, and this induces the entire map

We also provide a quick example of when a polyhedral divisor is unmarked but has unmarked subcones cones as the boundary.

Example 3.4.4. Let N be \mathbb{Q}^2 . Consider the polyhedral divisor defined by $\delta \otimes P_0 + (1, 1) + \delta \otimes P_1$ over \mathbb{P}^1 where $\delta = \langle (1, 0), (0, 1) \rangle$. We now insist that two dimensional cone is marked. However if we pick a ray of the tail fan, and calculate the dual we see that this does not satisfy of being semiample on the boundary, if the base curve was non affine.

Upon calculation of the affine ring this can be seen as a toric downgrade of the Atiyah flop, with the quotient corresponding to one of the two natural maps to \mathbb{P}^1 . To see the two flops the first is by unmarking the two dimensional cone and the other is given by the same polyhedral coefficients but now the tail cone is a tail fan with the ray $(1, 1)$ bisecting it. This corresponds to only one of the resolutions resolving the quotient down to the \mathbb{P}^1 .

Definition 3.4.5. *A fansy divisor a smooth curve C is a collection of n subdivision of \mathbb{Q} with markings \mathbb{Q}^+ , \mathbb{Q}^- , \mathbb{Q}^\pm or no markings at all.*

This is equivalent to a polyhedral divisor provided the the assumptions of ?? are satisfied.

Example 3.4.6. *One A_1 two A_3 .*

This defines a complexity one surface. In toric varieties full dimensional cones give rise to torus fixed point. Analogously, the same way for varieties of higher complexity every full dimensional subdivision of the plane gives rise to a toric fixed point. In the

case of surfaces these fixed points can be classified giving rise to three cases

- **Elliptic** - Around the fixed point in local coordinates, the torus behaves on all coordinates with positive or negative degree. These points are isolated.
- **Parabolic** - These always arise as blowups of elliptic points, these occur when in local coordinates, one of the coordinates is acted trivially upon by the torus. These points lie on a section of the map to Y
- **Hyperbolic** - These are where the the local coordinates are acted in positive and negative degree.

It is easy to see that Hyperbolic points correspond to a subdivision with $\delta = 0$, Parabolic correspond to an unmarked edge going to infinity and Elliptic to a marked point going to infinity.

3.5 Divisors in complexity one

We now limit ourselves strictly to complexity one, and the chow quotient Y will now be \mathbb{P}^1 . In the torus setting we know that divisors correspond to rays of the associated fan. Almost exactly the same is true in complexity one: divisors occur as torus invariant divisor, these correspond the codimension 1 polyhedral divisors or they are preimages of the \mathbb{P}^1 . These correspond to a polyhedral divisor \mathcal{D} going of to infinity in a direction, with $\dim(\delta) = \infty$ which for all $P \in \mathbb{P}^1$ we do not have $\mathcal{D}|_P = \emptyset$. Note that this also holds for higher dimensions, with a little bit of extra work. From this it is easy to derive the following theorem

Theorem 3.5.1 (?). *The Picard rank of a complexity one surface defined by a polyhedral fan \mathcal{S} is*

$$\rho_X = \# \text{ Number of parabolic lines} + \sum_{P \in Y} (\#\mathcal{S}_P^{(0)} - 1)$$

where n is the dimension and $\#\mathcal{S}_P^{(0)}$ is the number of points on this slice of the fan. Similar statements can be made in dimension n where the parabolic lines are replaced by x-rays. In a similar style to this we can classify Cartier divisors, we here make no pretense at proof or justification.

Definition 3.5.2. *A divisorial support function h on a divisorial fan \mathcal{S} is a piecewise linear function on each component of the fan such that*

- *On every polyhedron $\Delta \in \mathcal{S}_{P_i}$ it is a linear function*
- *h is continuous*
- *at all points h has integer slope and integer translation*
- *if \mathcal{D}_1 and \mathcal{D}_2 have the same tail cone, then the linear part of h restricted to them is equal*

We call a support function principal if it is of the form $h(v) = \langle u, v \rangle + D$, this corresponds to a principal Cartier divisor. We call a support function Cartier, if on every component with complete locus the support function is principal. In the case of Fany divisors, this just correspond to the edge with a marking. We denote h restricted to a component by h_P . We refer to a piecewise linear function with rational slope and rational translation as a \mathbb{Q} support function.

Theorem 3.5.3 (?). *Let X be the variety associated with the divisorial fan \mathcal{S} . There exists a one to correspondence between support functions support function quotiented by principal support functions and Cartier divisors on the complexity one variety. In addition there exists a one to correspondence between \mathbb{Q} support functions support function quotiented by principal support functions and \mathbb{Q} Cartier divisors on the complexity one variety*

Using the above languages we represent the canonical divisor as a Weil divisor, it has the following form

Theorem 3.5.4 (?). *The canonical divisor of a complexity one surface can be represented in the following form*

$$K_X = \sum_{(P,v)} (\mu(v)K_Y(P) + \mu(v) - 1) \cdot D_{(P,v)} - \sum_{\rho} D_{\rho}$$

Here $K_Y(P)$ is the degree of K_Y at P , and $\mu(v)$ is the smallest value k such that $k \cdot v \in \mathbb{N}$. While I have not stated the conditions for linear equivalence these can be seen in ?, and using these you can show that it does not depend on the choice of representative of K_Y . Note that given the singularities and varieties we are working with we know that our K_X will be \mathbb{Q} -Cartier. The fano index is clear and easy to derive from the singularities we have, so all that remains is to check on the conditions for a complexity one divisor to be ample.

Theorem 3.5.5 (?). *A support function h is ample iff for all P we have h_P is strictly concave, and for all polyhedral divisors \mathcal{D} defined on an affine curve we have*

$$-\sum_{P \in \mathbb{P}^1} h_P|_{\mathcal{D}}(0) \in \text{Weil}_{\mathbb{Q}}(Y)$$

is an ample \mathbb{Q} Cartier divisor.

Note that in reality $h_P|_{\mathcal{D}}$ may not be defined at 0 but we can extend the affine function to 0. We finish this recap on divisors by describing the Weil divisor corresponding to a Cartier divisor

Theorem 3.5.6 (?). *Let $h = \sum_P h_P$ be a Cartier divisor on \mathcal{S} then the corresponding Weil divisor is*

$$-\sum_{\rho} h_t(n_{\rho})D_{\rho} - \sum_{(P,v)} \mu(v)h_P(v)D_{(P,v)}$$

Here n_{ρ} is the generator of the ray inside the tail fan and $\mu(v)$ is as before. Note that is easy to see why we need this μ function. If you start with a closed subinterval

$[a, b]$ and try to work out what the corresponding affine variety is, we see that it just the toric variety defined by the cone $(a, 1), (b, 1)$, and then all your calculations can be done in the realm of toric varieties, however there you use the generator of your rays in the lattice, so you need the μ function.

We use the above note to easily calculate the minimal resolution of a complexity one surface. Note that we can split this across affine charts, in the first case if we have the affine chart corresponding to the polyhedral divisor $[a, b]$ then using the above point we can calculate this by the toric methods. In case two where we have a non marked edge going to infinity, we can split this into affine charts $[a_i, \infty)$ this is also a toric chart corresponding to the cone $(a, 1), (1, 0)$, so once again the resolution is toric. The final case is with a marked edge, however we can take a weighted blowup to resolve the elliptic point, then resolve the resulting singularities by the above methods. To calculate the intersection numbers on the resolution you can either use [Tim], ? or you can note that the only part that is not toric is the parabolic line, this is defined by glueing together charts coming from $[a'_i, \infty)$, here by smoothness $a'_i \in \mathbb{Z}$, this is isomorphic to the charts defined by $[\sum(a'_i), \infty)$ at P_1 and $[0, \infty)$ for all other P_i . Hence we see that the parabolic line is defined torically as the fan $(\sum(a'_i), 1), (1, 0), (0, -1)$ from this an easy derivation of the intersection number follows.

We can also draw out the graph of divisors on the minimal resolution. For example considering the following log del Pezzo from ?

$$\{-2, 0\} \otimes P_0 + \left\{-\frac{1}{2}\right\} \otimes P_1 + \left\{-\frac{1}{2}\right\} \otimes P_2$$

gives us the following resolution:

3.6 Algorithms

We propose two different algorithms for the classification of complexity one log del Pezzo surfaces. These both rely on several key facts

Lemma 3.6.1. ? *Let S be a non cyclic complexity one log terminal surface singularity. Then S has, upto isomorphism, a fan over \mathbb{P}^1 with coefficients*

$$\left[\frac{p_1}{q_1}, \infty\right) \otimes P_1 + \left[\frac{p_2}{q_2}, \infty\right) \otimes P_2 + \left[\frac{p_3}{q_3}, \infty\right) \otimes P_3$$

with (q_1, q_2, q_3) satisfying $\sum(1 - \frac{1}{q_i}) < 2$.

Proof. See ? □

We now use the following crucial lemma

Lemma 3.6.2. *Let S be a log terminal surface singularity of Gorenstein index l . Let E be an exceptional curve in the minimal resolution. Then $E^2 \geq -2l$ if it is not a trivalent curve and $E^2 \geq -3l$ if it is trivalent.*

Proof. Via the classification of log terminal singularities ? we have that E intersects at most three other exceptional curves. Denote the discrepancies of these curves d_1, d_2, d_3 , note that any d_i could be equal to zero. Also note that $0 \geq d_i \geq -1$. Denote the discrepancy of E by d . Then we have the formula $dE^2 + \sum d_i = 0$. This rearranges to $d = \frac{(\sum d_i)}{E^2} \leq \frac{-3}{E^2}$ as the singularity is log terminal. As $d \in \frac{1}{l}\mathbb{Z}$ we get $E^2 \geq -3l$. In the case of a non trivalent curve, we can assume $d_3 = 0$ and we see that $E^2 \geq -2l$. □

Lemma 3.6.3. *Given a complexity one log del Pezzo surface of index l then there cannot be more than $6l$ points where the polyhedral fan is not the tail fan*

Proof. Taking the minimal resolution of our log del Pezzo, this admits a map to a Hirzebruch surface \mathbb{F}_n . As we are contracting -1 curves our map is invariant under

the torus action. Hence this is a torus action on the Hirzebruch surface. Any series of complexity one non toric blowups on a toric surface correspond to blowing up points on a line of invariant points. We note that by the above lemma we cannot get a map to \mathbb{F}_n when $n > 3l$. Hence we the largest possible self intersection of a torus invariant curve on our Hirzebruch surface is $3l$ and the smallest possible intersection on our minimal resolution is $-3l$ so there can only be $6l$ blowups on the curve. \square

Remark. *In the case of index one, we know Du Val singularities only have -2 curves in the resolution hence this bound can be refined to four non general fibers.*

Lemma 3.6.4. *Consider the following polyhedral fan:*

$$\mathcal{S} = \begin{array}{ll} [a_1^1, a_2^1, \dots, a_{n_1-1}^1, a_{n_1}^1] & P_1 \\ [a_1^2, a_2^2, \dots, a_{n_2-1}^2, a_{n_2}^2] & P_2 \\ [a_1^3, a_2^3, \dots, a_{n_3-1}^3, a_{n_3}^3] & P_3 \\ [a_1^4, a_2^4, \dots, a_{n_4-1}^4, a_{n_4}^4] & P_4 \\ \vdots & \\ [a_1^{6k}, a_2^{6k}, \dots, a_{n_{6k}-1}^{6k}, a_{n_{6k}}^{6k}] & P_{6k} \end{array}$$

If \mathcal{S} defines a log del Pezzo surface X of index k then $\sum_j [a_1^j] \geq -6$ and $\sum_j [a_{n_j}^j] \leq 6$.

Proof. Let Y be the minimal resolution of X , and consider \tilde{Y} . This has two parabolic curves E_1 and E_2 corresponding to $[-0, \infty)$ and $(-\infty, 0]$. The self intersections of these curves are $\sum_j [a_{n_j}^j] \leq 6$ and $\sum_j [a_1^j] \geq -6$ respectively, and these values have to be less than $6k$. \square

Just as in the case of Gorenstein index one, where the singularities are formed of -2 curves. There is an explicit way to classify the resolutions of singularities of higher index.

Lemma 3.6.5. *A singularity of index n which is non toric log terminal singularities*

can be described by one of the following polyhedral divisors

- $[-\frac{1}{2}, \infty) \otimes P_1 + [\frac{1}{2}, \infty) \otimes P_2 + [\frac{n}{m}, \infty) \otimes P_3$
- Finite E_6, E_7, E_8 case

Proof. We note that for the canonical divisor to be Cartier the corresponding slope function has to have integral slope and $h_P(0) \in \mathbb{Z}$ for all $P \in \mathbb{P}^1$. We note the slope for a polyhedral divisor of the form $[-\frac{1}{2}, \infty) \otimes P_1 + [\frac{1}{2}, \infty) \otimes P_2 + [\frac{p}{q}, \infty) \otimes P_3$ is $\frac{1}{p}$. Hence p divides n where n is the index of the singularity. We now note $h_{P_1}(0) = -\frac{-1}{2} + \frac{1}{2p} = \frac{1}{2}(1 + \frac{1}{p})$. Now if p is odd this becomes a fraction $\frac{a}{p}$ and if p is even this becomes $\frac{a}{2p}$. Now $h_0(P_3) = \frac{q-1}{q} + \frac{p}{q} \frac{1}{p}$, this is always just 1. Hence for every $kh_P(n)$ to be an integer for every $P \in \mathbb{P}^1$ and $n \in \mathbb{Z}$ we need k to be a multiple of p if p is odd and a multiple of p if p is even.

Do the E_6, E_7, E_8 case. □

Remark. *This imposes stricter bounds on the number of non generic fibers a complexity one surface of index n can have than Lemma 4.6.5 and enables you to put bounds on per the singularity.*

We also need a bound on what possible toric singularities can occur and the possible actions on them.

Lemma 3.6.6. *Let X be a non toric non smooth complexity one log del Pezzo surface. Then there is at least one elliptic point and at least one of the elliptic points, P_1 , is a singularity. We can describe P_1 locally by a cone $\sigma \subset N \cong \mathbb{Z}^2$ and a ray $v \in N$. Then v corresponds to a lattice point on the minimal resolution of σ . Equivalently the minimal resolution of X has at least one parabolic line.*

Proof. Let Y be the minimal resolution of X . Then X admits an equivariant map to \mathbb{F}_i as every -1 curve on Y is torus invariant. Hence Y is constructed by a non toric blowup of a toric surface. Considering the first non toric blowup, we are blowing up

a point P on a torus invariant curve C . Clearly C is a torus invariant curve in the minimal resolution of X .

To show C is not a curve on the surface we note that if C has to be a torus invariant curve on the Hirzebruch surface \mathbb{F}_i , otherwise we would blow up a -1 curve at a general point and the resulting curve would have to be contracted. If C was the positive section then then the contraction of the negative section would give a singularity with the desired properties. If C was a fiber, C needs to be blownup at least twice to be non toric, which would make it have negative self intersection, meaning it would have be contracted. This would once again give a curve with the desired properties. \square

We finish with the following observation that helps shorten calculations. Let X be a complexity one surface with the following polyhedral fan:

$$\begin{aligned} P_1 & [a_1, \dots, a_n] \\ P_2 & [b_1, \dots, b_m] \\ P_3 & [c_1, \dots, c_o,] \\ P_4 & [d_1, \dots, d_{p-1}, 0] \end{aligned}$$

and a marking \mathbb{Q}^+ . Also assume that the minimal resolution of X contains a curve E which is pointwise fixed by the action and which is contracted to elliptic point at positive infinity.

Let h be the piecewise linear function corresponding to $-K_X$. Then $h_P|_{[0, \infty)}$ is defined by a unique value $u \in \mathbb{Q}$. If $-K_X$ is ample then the only possible values for d_{p-1} are the values $\frac{p}{q}$, with $q > 0$, such that $\frac{q-1}{q} < u \frac{p}{q}$ this is to preserve convexity.

As there are a finite number of log del Pezzo surfaces, up to deformation, with Gorenstein index k there can only be a finite number of singularities S which can occur on such a surface.

The algorithm proceeds iteratively, we start with the polyhedral divisor $w_1 \otimes P_1 +$

$w_2 \otimes P_2 + w_3 \otimes P_3 + \sum_{i=4, \dots, 6k} 0 \otimes P_i$. We will show how to bound the values w_i later. We now wish to extend this by adding an extra cone into one of the fibers such that $-K_X$ is still ample and the surface can be further compactified into a log del Pezzo surface of Gorenstein index k . We show there are finitely many choices and we can repeat this process until it terminates.

This corresponds to the following. Given a polyhedral fan \mathcal{S} with tail fan $[0, \infty)$ with the following values

$$\mathcal{S} = \begin{array}{ll} [a_1^1, a_2^1, \dots, a_{n_1-1}^1, w_1] & P_1 \\ [a_1^2, a_2^2, \dots, a_{n_2-1}^2, w_2] & P_2 \\ [a_1^3, a_2^3, \dots, a_{n_3-1}^3, w_3] & P_3 \\ [a_1^4, a_2^4, \dots, a_{n_4-1}^4, 0] & P_4 \\ \vdots & \\ [a_1^{6k}, a_2^{6k}, \dots, a_{n_{6k}-1}^{6k}, 0] & P_{6k} \end{array}$$

We are trying to find all values $a = \frac{p}{q}$, such that the polyhedral divisor $[a, a_1^i]$ is a toric singularity and the fan \mathcal{S}' equal to

$$\mathcal{S} = \begin{array}{ll} [a_1^1, a_2^1, \dots, a_{n_1-1}^1, w_1] & P_1 \\ [a_1^2, a_2^2, \dots, a_{n_2-1}^2, w_2] & P_2 \\ [a_1^3, a_2^3, \dots, a_{n_3-1}^3, w_3] & P_3 \\ [a_1^4, a_2^4, \dots, a_{n_4-1}^4, 0] & P_4 \\ \vdots & \\ [a, a_1^i, a_2^i, \dots, a_{n_4-1}^i, 0] & P_4 \\ \vdots & \\ [a_1^{6k}, a_2^{6k}, \dots, a_{n_{6k}-1}^{6k}, 0] & P_{6k} \end{array}$$

can still be compactified into a log del Pezzo surface of index k . While not drawn above in the fan i can be 1, 2 or 3. Let $a_1^i = \frac{r}{s}$. As the we are dealing with cones

with tail cone 0 we know this corresponds to a locally toric singularity so we have the following picture:

Toricpicture!!!!

Every possible choice of p, q lies along a line L_a , as the curve joining them has to be a -1 curve via Lemma ???. We wish to show that there are only finitely many values along the line L_a which are valid. We denote by L_0 the line parallel to L_a going through the origin. We note that if L_a crosses the x axis there are only finitely many values, denote by v the ray generating this line. If L_a does not cross the origin, denote the points on the line v_0, v_1, v_2, \dots . This forms an infinite family. Note that if P is a point such that v_i, P gives a Gorenstein index k singularity then (v_{i+k}, P) also gives a Gorenstein index k singularity. In fact every possible point P' such that (v_{i+k}, P') is a Gorenstein index k singularity is of this form. We now split into two cases, the first is that the line L_0 is the x -axis. In this case, let $v_i = (t_i, u_i)$ then as i tends towards infinity $\frac{t_i}{u_i}$ limits towards $-\infty$ so we get a bound via Lemma MaxLength. If L_0 is not horizontal then considering the points v_i as i limits towards infinity, then the points P_i such that (v_i, P_i) is a Gorenstein index k singularity are eventually all positive and all have y coordinate larger than the y coordinate of any of the w 's. Hence they cannot join together, and hence cannot occur.

All that remains is to bound the possible singularities we have started with. However this follows by a similar logic. They lie in infinite families. Once the singularity gets too large, the bounds become unfeasible and they cannot occur.

As an example we illustrate how this can classify Gorenstein log del Pezzo surfaces which have complexity one.

Example 3.6.7. We start with the Gorenstein index $k = 1$, i.e the only singularities are Du Val. We know there is a singularity which has an action which corresponds to a curve on the minimal resolution. We iterate over all possible singularities and all possible actions until we can show they do not exist. We illustrate this in the

case that the singularity with which the action corresponds with a ray in the minimal resolution is an A_n singularity. We assume that this singularity has polyhedral divisor with tail cone $[0, \infty)$. From now on we assume this without stating it.

To make this easier we make two observations. The first is that if a fiber over a point P_i is $[a_1 = \frac{p_1}{q_1}, \dots, a_n = \frac{p_n}{q_n}, 0]$ then $q_i = 1$. This follows via the above remarks, first, we know we get an A_m singularity given by $(0, 1), (p_n, q_n)$. Then, via the stated properties of our singularity, we have the slope of $h_P|_{[0, \infty)}$ is -1 . So we need $\frac{q_n-1}{q_n} < \frac{-p_n}{q_n}$ which implies $p_n + q_n < 1$, hence if $q_n > 1$ then $p_n < -1$. Now every point on the line connecting (p_n, q_n) to $(0, 1)$ has to satisfy this inequality. In particular there is a point $(-1, a)$ on this line, with $a \in \mathbb{Z}$, satisfying the inequality, hence $a \leq 1$. As $a > 0$ for $q_n > 0$ we have the only possible value of a is one. This corresponds to $q_n = 1$.

The second observation is let $\mathcal{D} = \frac{1}{u} \otimes P_1 + \frac{1}{v} \otimes P_2$. be a polyhedral divisor with tail cone $[0, \infty)$. We can assume without loss of generality that $u \geq v$. Then if $u > v + 2$ and $v \geq 2$ then there are no complexity one Gorenstein log del Pezzo surfaces which contain \mathcal{D} as a polyhedral cone. We note as $u, v \geq 2$ we have the only possible polyhedral fans over P_1 are $[0, \frac{1}{u}]$ and $[\frac{1}{u}]$, similarly for P_2 . Viewing this from a toric perspective the only points that can be connected to $(1, u)$ or $(0, 1)$ while preserving the necessary convexity are less than $-v$. This implies as a complexity one surface this would need a denominator on another fiber less than v , but this cannot happen.

- A_1
- A_2
- A_3
- A_4
- A_5 **Singularity**

This has several possible actions taking the first us the polyhedral divisor

$$\begin{aligned} P_1 & [a_1, \dots, a_n, \frac{1}{5}] \\ P_2 & [b_1, \dots, b_m, 1] \\ P_3 & [c_1, \dots, c_o, 0] \\ P_4 & [d_1, \dots, d_p, 0] \end{aligned}$$

The only choices for the first row are $[0, \frac{1}{5}]$ and $[\frac{1}{5}]$. We call this case *a* and case *b*.

In case *a* if there is another elliptic point it has to be arising from a toric singularity with coordinates $(0, 1)$ and $(-1, u)$ with $u \leq -4$ and the subtorus once again corresponding to the horizontal line. This cannot happen as every other row can only have denominators equal to 1. So this case does not occur. Note a non toric singularity cannot occur otherwise the slope on the tailfan $[-\infty, 0)$ would be one and this would not be convex on P_1 .

For case *b* we have exactly the same argument that it would have to be connected to a singularity with denominator greater than 1, hence cannot occur. So this does not occur.

The next case is

$$\begin{aligned} P_1 & [a_1, \dots, a_n, \frac{1}{4}] \\ P_2 & [b_1, \dots, b_m, \frac{1}{2}] \\ P_3 & [c_1, \dots, c_o, 0] \\ P_4 & [d_1, \dots, d_p, 0] \end{aligned}$$

Once again two cases for P_1 , $[0, \frac{1}{4}]$ and $[\frac{1}{4}]$. If it is the first case then the denominator has to be greater than 2 so does not occur. In the second case there is only one possibility: the other elliptic singularity is given by toric coordinates $(1, 4)$, $(-1, -2)$. The only way to get a denominator greater than 1 is on P_2 and the only choice is if

this is the original $\frac{1}{2}$ hence we get

$$\left[\frac{1}{4}\right] \otimes P_1 + \left[\frac{1}{2}\right] \otimes P_2 + [0, -1] \otimes P_3$$

The final case is

$$\begin{aligned} P_1 & [a_1, \dots, a_n, \frac{1}{3}] \\ P_2 & [b_1, \dots, b_m, \frac{1}{3}] \\ P_3 & [c_1, \dots, c_o, 0] \\ P_4 & [d_1, \dots, d_p, 0] \end{aligned}$$

This leads to a lot more cases, as follows. Once again possible choices for P_1 and P_2 are $[0, \frac{1}{3}]$ or $[\frac{1}{3}]$. Once again denoting these by case a and case b . In case a it needs to connect to a point with denominator $u \in \{2, 5, 8 \dots\}$, however it is impossible to construct any of these denominators, so this does not occur. In the case b , we either have the A_1 singularity with coordinates $(1, 3)$, $(-1, -1)$ or the A_2 singularity given by $(1, 3)$, $(-2, -3)$, other values result in non compatible denominators. If we had the singularity given by $(1, 3)$, $(-1, -1)$, then the polyhedral divisor over P_2 would have to be $[0, \frac{1}{3}]$ which we have already shown cannot occur. If we have the A_2 singularity then this involves the only way this can be constructed is via

$$\left[\frac{1}{3}\right] \otimes P_1 + \left[\frac{1}{3}\right] \otimes P_2 + [0, -1] \otimes P_3$$

This finishes the A_5 case.

A_N Singularity for $N \geq 6$

This results in a singularity given by surface given by

$$\begin{aligned} P_1 & \quad [a_1, \dots, a_n, \frac{1}{u}] \\ P_2 & \quad [b_1, \dots, b_m, \frac{1}{v}] \\ P_3 & \quad [c_1, \dots, c_o, 0] \\ P_4 & \quad [d_1, \dots, d_p, 0] \end{aligned}$$

We split this into three case

- a) $u = v$
- b) $u = v + 1$
- c) $u = v + 2$

Every other case is covered by our discussion at the beginning or the example. We note that which of these cases occur on the value of N . We note as $N \geq 6$ this implies $u \geq 4$ and $v \geq 3$.

In case a), the only denominators that occur which are less than or equal to v are $\frac{1}{u-2}$ and $\frac{1}{u-1}$ however as $u \geq 3$, as $N \geq 6$ we have neither of these values are equal to u or 1 so this cannot occur.

In case b),
